Can someone help me with a plan for a 900mhz antenna to help me extend my base to phone range.

Thanks William KG4JMW

hey william
first off i would worry about extending a cordless phone like that you could have even more people able to hack your phone line and make calls on your bill and also would make it even easier for scanner listeners to pick up your conversations but if you really need to do this go to www.directivesystems.com they carry 900MHZ yagis in a wide range of sizes i wouldnt suggest building one cause of the fine line that is required in your cuttings and its a pain to build a matching section for one besides the 900mhz yagis arnt that expencive
good luck

And if I am not mistaken, this little slotted socket can be screwed out of there.
If the other end will do the same thing, they might be able to be swapped--pin in coil and socket in the base. I have done this in the past with AS antennas
when converting to/from NMO mounts. In some of the AS NMO mounts, the pin in the coil is spring-loaded, and it will screw out as well. I have then substi-
tuted the slotted socket to to coil to mate with other kinds of mounts.

Also, I have removed the socket, found a small screw that would screw into the bottom of the coil where the socket was, and was just the right size to make
contact with/fit into a socket on the mount. Sometimes, with a little imagination,
you can make it work.

That's my argument, Reg. Changing the differential impedance

can change the common-mode currents. Thus, they are not
unrelated.

So you discourage common-mode current so that it prefers to go

somewhere else? :-)

10. SIMPLEST ANTENNA-TUNER

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-01 02:55:57 UTC
From: All The News That Doesn't Fit <NY-Transfer-News@blythe.org>
Message-ID: <9p8lkb$9mc$1@news.panix.com>
Source record: 156761

SIMPLEST ANTENNA-TUNER
Arnie Coro, radio amateur CO2KK

http://www.radiohc.org/Distributions/arnie.html

Arnie's Simplest-to-Build Antenna Tuner

Parts List: Here is the list of materials: one ferrite rod, of the ones that are cylindrical in shape, and of a length of about 4 inches or more. You will also need two identical variable capacitors. I prefer using air spaced variables taken from defunct old vaccuum tube radios, the ones you can still find at junkyards and garage sales. If you see vaccuum tubes inside, buy them, as each radio has a very nice air spaced variable capacitor. You will also need about 1 meter (3 feet) of standard, plastic-insulated wire.

Assembly: The tuner is made in the following way: First, you cover the ferrite rod with one layer of vinyl plastic electrician's tape. Then, you wind 10 turns of the plastic insulated speaker wire, spaced one turn diameter from each other. Connect the stator plates of the variable capacitors -- those are the fixed ones -- to each end of the wire, and connect the two capacitors' rotor plates -- the movables ones -- to each other and to your radio's ground connection. Now connect the antenna to one side of the ferrite rod coil where it is joins one of the capacitors' fixed plates. The other identical side goes to the radio's antenna input. And... you have a very nice, easy-to-build PI network antenna tuner! Tune your receiver to the 49 meter or 6 megaHertz band, look for a weak station, and then slowly turn first one capacitor, and then the other for maximum signal. That's it!

Variations: You may want to experiment -- remember that the radio hobby is an experimental one -- and wind more turns, say about 20 tightly wound, and see if you get improved reception at lower frequencies. With a standard 4-inch rod and 15 turns, using two 365 picofarad surplus variable capacitors, my low-cost PI antenna tuner will provide a good match between about 5.5 and 29 megahertz. Remember that the lower the frequency, the more capacitance you will need; in other words, the tuner will reach resonance with the capacitors' plates fully meshed into the fixed plates. Higher frequencies will tune with the capacitor plates out, with the maximum frequency reached when the two capacitors' plates are fully out.

I added a little five-position, single-pole switch and made taps to the coil in a later model. So, if you can get hold of a similar 4, 5 or 6 or even 10-position switch, you can add this feature to make a still-more-flexible antenna tuner. This simple tuner helps reduce image frequencies that are a problem with less expensive radios, and it also

stops some intermodulation problems that make reception difficult in those receivers, too... I have used my prototype with a little amateur radio QRP 10-watt single-sideband phone rig with excellent results, as well.

You can learn more about PI network antenna tuners by visiting your library and looking at the antennas chapters of any radio handbook.

Since you are posting without your actual name and email address, I
will respond here.

Yes, they are discontinued at Radio Shack. They are not available at
the RS stores with a few...VERY FEW...exceptions. If you can find one
at the Radio Shack store, by all means, buy it. If not and you want
one, I have one.

I hope you are not a business man. If you sell items for what you
paid for it, you will go broke quickly. Anyway, thanks for your very
informatitive response to a FS: posting.

Randy

13. 60khz antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-01 06:02:36 UTC
From: "john sindorf, m.d." <john.sindorf@worldnet.att.net>

Source record: 156764

My first post here.

I recently bought a digital clock which is able to pick up WWVB, and thus have "perfect" time. However, the transmitter is in Fort Collins, CO, and I am in Bellevue, WA (near Seattle), probably at the far reaches for normal reception. I seem to recall from conversations with my now passed father, who was a long time ham, that a "reflector" could be constructed that would improve radio signal reception significantly. Does anyone here know the quick and dirty of this? Possibly point me in the right direction? Is this for real, or did I just make this up from bits and pieces of long past conversations?

I do get the signal, about once a week, usually when it's cloudy and rainy, so I know it works, I just need to improve the antenna somehow. The antenna is internal, so the reflector idea is about the only thing I can think of that would improve my reception.

Thanks for your help,

John

Hi John,

It sounds like your clock is working just fine as it is. You say it
works about once a week. Actually that is how long it takes for the
clock to slip out of sync before the automatic correction kicks in.
That is, unless the corrections amount to more than 3 or 4 seconds.

An antenna's size is related to the frequency of operation through its
inverse relationship of wavelength. That means that an antenna
suitable for 60 KHz would be on the scale of a thousand meters.
Clearly your clock's antenna comes no where near that long, it instead
uses a loopstick antenna. Take a hint that you may improve on the
antenna, but that you may not have an antenna problem.

The simple solution is to move the clock to another wall (a 90 degree
change some times does the trick). There have been many posts over
the years here for what you ask. Most later report the clock was
working fine in the first place. Accuracy can get pretty boring....

When I was in Tricky Dick's Canoe Club, my prize posession was an HP
Atomic Clock with accessories for its calibration. I could hear WWVB
out in Charleston SC quite well on a 20' whip. That whip was 100
nanoseconds away from the clock and this delay had to be part of the
calculations as I maintained the standard accurate to absolute time
within 100 nanoseconds (100% error just in the transmission line).

However, I could not get an accurate reading from Ft. Collins on
demand. The frequency of my standard, 10 MHz and that of WWVB, 60
KHz, are not the same, and are harmonically related in the extreme.
As such, every 17 minutes or so, the two frequencies would both
exhibit a simultaneous zero crossing or TOC (Time Of Coincidence) that
served as the heartbeat of time (defined by the Naval Observatory).
My clock was never in error (maybe 50 or 60 nS) - no surprise and

boring.

Haro wrote:
"How can I make a good earth and do I have to have one?'

A balanced antenna such as a dipole needs no earth connection for performance.

An unbalanced antenna system includes the earth or a reasonable facsimile.

Antenna and earth connections in terms of wavelength are important. So, the length of wire connecting a wireless set in a loft to the earth may or may not be important. For example, an elevated unbalanced antenna may include a counterpoise which obviates an earth connection as a necessity for efficient operation. You may require a safety ground to avoid electrocution and electrical surge damage.

How to make a good earth connection includes the same methods as making any good r-f electrical connections plus taking into account the effect of conductor length on its impedance.
What is necessary depends on the situation.

Best regards, Richard Harrison, KB5WZI

Sylvan:
For what you are doing, you really need high volume/low pressure (Vacuum cleaner output, or just a squirrel cage blower) rather than high pressure, low volume (air compressor). BTW, a squirrel cage connected into a 'plugged' duct runs under less load than when it is running in open air.

Your incorrect argument is a ~50 ohm differential mode impedance
results in better balun performance.

In an effort to justify that false idea, you are spamming the
newsgroup with Chipism's.

Pete, that is probably the best simple overview of information management I have seen to date. So few of today's technologists seem to understand the critical difference between throughput and data transfer rate.

As a longtime professional communicator and ham of 45 years tenure, I know very well how critical it can be to be able to dig a few words out of the noise as compared to having the ability to transfer many pages of data nearly instantly. Passing INFORMATION is the key. Sometimes it takes very little throughput to get the job done.

As you said, Shannon showed what is possible, not what is needed. Confusion abounds regarding their relationship. Many technologies and applications take advantage of what is possible. But it is very clear that such data rates are not needed in all applications.

Yeah, and a couple years ago Cecil berated me quite soundly for not
"knowing" that it was all simple Ohm's law. Tsk, tsk.

Reg, you're in tune with my outlook, in all the above cases. :-)

In over 40 years of ham and professional radio work I never came
across the term "common mode currents" WRT antennas until I started
reading this NG.

Of course every ham knows about "RF on the feedline".

Dick

> I have my setup in the loft so I have no good earth, how can I make a good
> earth and do I have to have one?
==========

The main handicap of an antenna in the loft is not that you can't get a good earth but because it is not very high above ground anyway. The ground actually consists of the domestic hot and cold water pipes, plus the central heating system, plus the 60Hz power wiring, plus phone cables, plus the microwave oven, plus anything else which is grounded at HF.

The whole lot bunched together is not a bad ground. But an antenna in the loft is not very high above it. And height counts very much for radiating purposes. It must also be remembered a loft antenna is screened to an appreciable extent from the outside world.

A lot depends on what frequencies you would like to transmit on.

At the higher freqs, 10 MHz and above, you may be better off using a balanced, center-fed antenna arrangement fed via twin line. At lower frequencies an end fed wire arrangement may be better or you could consider a magloop. These antenna do not need a ground. A centre-loaded dipole will perform quite well in the loft.

On the lower HF bands just try to get as many amps as you can into the longest and highest wire you can while the antenna is tuned against the best ground you can manage.

In a loft, for reasonable efficiency, you should consider yourself restricted to one band only, not more than two bands.

On the other hand, you will very likely get around in some sort or another on all bands. In general the higher the frequency the better you will do.

Get on the air and see what happens ! You are sure to be OK on at least one band. Remember it is height and length what matters.

Actually, what I said is that the higher the load impedance

the 50 ohm balun sees, the worse the common-mode currents are
likely to be. I'm setting up an experiment to try to verify
that statement. I will report the results. Remember, you said
common-mode currents are *unrelated* to the differential
impedance. If the common-mode currents change as the differential
load is changed, your statement is false.

Another person who thinks that common-mode currents remain constant

when the differential load impedance is changed? IMO, such an
occurrence would border on the supernatural. I'm setting up an
experiment and will report the results.

Many, many years ago, at Shannon's first University, class was let out to
listen to him give a talk. The EE Chairman (or possibly it was the
Professor who had been the Chairman when Shannon was an undergraduate) got
up to introduce Shannon and remarked that he (the Chairman) had recommended
that Shannon go to MIT for graduate work because it offered more
opportunities than UofM. (No longer the case!) Most recalled from the talk
was Shannon's remark that if your channel did not have some errors you were
using too much power. ...added to Costa's paper in December 1959 (Proc of
the [beloved]IRE) what needed to be done was demonstrated - took some time
before it was realized.
So-call CW (which it sure is not) will always be the ultimate human to
human, low SNR communication mode. Shannon understood....

29. Screwdriver Antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-01 21:50:27 UTC
From: Jerry Oxendine <joxendi@bellsouth.net>
Message-ID: <IF9u7.83121$Dz6.1653824@e3500-atl2.usenetserver.com>
Source record: 156684

Hello Group,

I make my own version of the screwdriver antenna, as some of you already know. Called the "Carolina Cyclone", it incorporates features not usually found on the DK3 variants. While the DK3 antenna IS an excellent antenna and, certainly outperforms hamsticks and Hustlers, it does have some drawbacks. The "usual" screwdriver often uses PVC for the non-metallic components, and this, of course, is not the best material for coil forms in particular.

The Carolina Cyclone is a full 2" in diameter, uses black Nylon for all its parts except for the mast. The Nylon is a very tough, and UV resistant material. The windings are #14 silverplate wound at 8 TPI whereas the cheaper SDs use #16 wire wound at 10 TPI. The result is a better form factor, a much better "Q", which makes for getting one's signal thru where others fail in the QRM. The generic screwdrivers use Butyl for coil covers which is thin and will crack after about a year in the sun/weather. The Carolina Cyclone uses Lexan coil covers that will not fade, crack, or discolor. The walls are 1/8" thick. The stuff lasts for years and years. Fingerstock is extra heavy duty, being that each individual finger is a full 1/4" wide, and has extra tension to assure that contact is main-tained at all times. I see some SDs that have excessive "wiggle" or play in the coil when fully extended. This is not the case with the Carolina Cyclone because the loading coils are machined by a professional plastics supplier and are matched to the 2 1/4" OD aluminum mast with a "tail" that extends below the wound portion of the coil and fits precisely to prevent play. While the coil has a bit of play, it amounts to only about 1/16" in any direction--almost imper-ceptable. After all, if the thing fit TOO closely it might bind or catch. Finally, if you "race" a Carolina Cyclone (time how long it takes to go from 75 to 10 meters) with some of the others, you'll find that it fairly flies, reducing the time it takes to QSY. Want to run an amp? Don't worry about it, I warrant the antenna up to 800 watts. It won't even notice it! A PVC-based screwdriver will shrink it's loading coil in nothing flat on this kind of power--leaving

the poor
operator with an expensive "slinky" toy!

I am sort of puzzled as to why some manufacturers charge over $300-$400
for their screwdriver products. For $240 (yes, I had to do a small increase
due
to costs of material), you get a very tough, high performance, and cost
effective
antenna system that will please the most discerning mobile DXer. Some of my
antennas are in service with Civil Air Patrol, as well as with hams from
Maine
to California.

I build these fine antennas to supplement my retirement income, and I have
the
time to see that they are up to exacting specifications. You will receive
all nec-
essary parts and instructions (less whip) to get your system up and running
in
short order. I am also available for email questions.

If you are considering HF mobile, or are thinking of upgrading your mobile
antenna, I ask you to consider the Carolina Cyclone. Yes, you can get 'em
cheaper, but you won't get 'em BETTER!

Thanks much for everybody's time.

Jerry

J:

I take it that like Claude Shannon, you also hail from Michigan.
Michiganites should be proud, not only do they produce great
automobile industrialists but also great mathematicians and communications
theorists. Shannon was a small town boy from small town Michigan.

Shannon was undoubtedly a genius of the first order, yet still very
approachable and personable. He passed away in February 2001 after a long
bout with Alzheimers.

Did you note that the IEEE Information Theory Society has erected and
dedicated a statue and memorial in his honor in the town square in Gaylord,
MI, where he grew up. His wife Betty was there for the dedication along
with several of his former students and colleagues.

In my view, his celebrated channel capacity formula C = W log(1 + S/N) ranks
right up there with V = IR, and E = mc^2.

Joseph, KJ5O wrote:
"Any thoughts on what happened there?"

Many variables are unknown, so there is no rigor here, but an estimate can be made.

An FM receiving antenna whip can be various lengths but at a foot away from a 2-meter transmitting antenna it can have a large mutual impedance and deliver a large voltage.

What is 10 watts in 200 ohms? About 45 volts!

What about a nearby FM broadcast station?

The 1/2-wave dipole is the FM broadcast reference antenna. 1 KW in a dipole is supposed to produce an FM signal of 137.6 mV/m from a reference dipole at one mile.

Suppose 100 KW were transmitted instead of 1 KW. 1.38 volts per meter would result at one mile. Suppose you had a transmitting antenna gain of 6 db. That gain would increase the signal from 100 KW to 2.76 volts per meter at one mile. Doubling the voltage represents four times the power, thus a 6 db gain.

Suppose you could have your car antenna parallel with the transmitting antenna and only 1/2 mile away? Again you would experience a 6 db increase in signal and double the volts per meter. This strength would now rise to 5.52 volts per meter.

The 45 volts we guess for the 10-watt source 1 foot away is a lot more than the 5.52 volts we guess for an ERP of 400 KW at 1/2-mile distance.

Best regards, Richard Harrison, KB5WZI

I have several "atomic" clocks, as they're sometimes called, including a watch. All mine work just fine.

Placement is often critical. If you have it mounted on a wall, there may be hidden pipes and wires in the wall that will affect reception. The sheetrock in my kitchen has foil on the back as a moisture barrier - a clock mounted on this wall will never sync up.

Try placing the clock on a window sill that's facing Colorado, probably SE for you, and see if that lets it sync up every evening. Usually the antenna is mounted parallel to the front panel display of the clock. Many clocks only look to sync up around 1AM Eastern or local time; others try every 6 hours or more. The best 60kHz propagation seems to be around 0400Z - 0600Z. At one time WWVB's web site had some signal strength "maps" - this is where I found the optimum reception time. I live in Connecticut, which is probably farther away from WWVB than you are, and get good signals year round.

Did you check the connections on the am/fm radio? Something could have come loose and given these symptoms. Secondly, the am/fm could have developed a problem independent of your transmitter.

Good luck,

Bill, W4WNT

Hi Will!
As You are in the US, I dunno.

BUT, had You been on this side of the Atlantic, I would say
"Use the ordinary flat 230 V cable, that can be found in
nearly every store". It is a working replacement (altough,
not exacly 75 ohm, it varies a bit, but close enough for
a feeder - if used as a transformer, some measurement would
be neccesary. I also think it might be a bit lossy on VHF.

Something quite look-alike (127V dual cord) can be found
in a store near You?

Hi Will,
are you sure it should be 75 ohm ? Common twin-leads are 300-ohm,
450-ohm and 600-ohm; I know a 200-ohm and 150-ohm twin-leads, too. The
less is the impedance, the more close must the two wires be. 75-ohm
seems to be impractical.

I suppose that it's possible that the am/fm developed an unrelated
problem... but the timing is just so coincidental...

After checking again the sensitivity of the am/fm radio, I realized that
I didn't get most of my radio functions back... I was just in a good
area for reception...

Since the truck is only a year old, I think I'll take off my antennas
and bring it by the dealership for a warranty repair/replacement.

Thanks for the suggestions guys.

I suspect that 75-ohm twinlead has gone the way of the dodo bird.
When I was first licensed (about 35 years ago), Belden used to
manufacture a 75-ohm transmitting twinlead. But, a search of
their web site shows nothing now.

Sorry.

73,
Bob

Regular 110VAC zipcord is about as close as you can come nowadays.

45. Thesis about multiband fractal antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-02 16:12:22 UTC
From: rafahol@hotmail.com
Message-ID: <402c1c32.0110020812.21f1a6f6@posting.google.com>
Source record: 156698

Hello,

I'm a student studying electrical engineering at the university of Technology of Delft (The Netherlands) and in november I started to do my thesis. The title of my project is "Analysis and design of a multi-band antenna for mobile-satellite and radar communication". My focus lies on determining what type of antenna is best suited for use in mobile terminals.

I discovered that three type of antennas are used nowadays for wireless communication (monopole, patch and helical ones). But then I discovered a few pages where they were designing and investigating a total new type of antennas named "Fractal". So I decided to search more information on the internet and discovered that the university of Barcelone (Spain) is very interested in this type of antennas and that they are have group that is investigating that type of antennas. Also they have won a prize (with a novel dual-band antenna for base-stations).

What I would like to know is if it is possible to design a Sierpinski gasket for mobile terminals in terms of the size?

How can I find more information of fractal antennes on the web of fractal antennas? I ask this questions) because my tutor is very interested in this type of antennas because little is known and they are currently no investigations of this type of antennas.

A few questions are: how can I calculate the graph of the S11 (dB) versus the frequency? What formulas are used? And are there software programs available to design and calculate the radiation patterns of these type of antennas rapidly?What is the best method MoM or FDTD for simulating such type of complex structures.

With all the information and website and examples of thesis, still I can't continue. In the past months I simulated these type of antennas using ADS of HP Momentum but the simulations don't agree very well with the measurements given in the literature. Is there another software package which could handle these type such as the Sierpinski gasket?What's the best and easiest way to draw such a Sierpinki gasket patch antenna?

I would like to thank you already for answering my questions

Sincerely, Rafael (student on this thesis)

Will, KD7BFX wrote:
"I am looking for some 75-ohm twin-lead."

That 75-ohm balanced feedline was appoximated by various pairs in the 1930`s. It was in demand for doublet receiving antennas, found to have less noise due to their balance, than the more common random length wire used with a ground connection.

Various twisted (for better balance and convenience) pairs were used and assumed to have a surge impedance near 75 ohms. There was plenty of twisted a-c drop cord available then. Better yet, was twisted No. 14 wires insulated with weatherproof rubber that you probably could get from your friendly telephone man. Then, there was special r-f feeder wire designed for use with aerials, but not as available as the a-c and phone wires.

I haven`t checked loss and impedance of common parallel wire cables, but expect that a check woul turn up some that have acceptable r-f loss and an impedance close enough to 75 ohms.

Best regards, Richard Harrison, KB5WZI

47. Horizontal "V" ?

Newsgroup: rec.radio.amateur.antenna

Gentlemen,

I am putting up a dipole, strange configuration out of
necessity. It will be a horizontal "V" and perhaps inverted.
I must place this in the corner of my lot and my lot because it ain't
wide enough for a normal flattop or Inverted "V", so I will have a
riight angle at the feed point and if it helps SWR, I can lower (or
raise) the ends.
My question is am I just going to burn the grass or will I have
a pretty good chance for an omnidiretional antenna?

Any help appreciated. Please reply to lynyrd@netdoor.com so that I
won't miss it.

73,
Butch KF5DE

For whatever it is worth, if you use zip cord as a substitute for 75-ohm twin lead, on page 15-3 of the arrl antenna book, it says zip cord can be a bit lossy. You could get away with 100 feet of it on 80, and 50 feet on 40, but for longer lengths and higher frequencies, the losses become pretty big. (They, by the way, tested an 18 guage zip cord as having an impedance of around 105 to 107 ohms.)

>Sincerely, Rafael (student on this thesis)

Hi Rafael,

You have reached the right place for such discussion, possibly more
than you would have expected initially.

This is a very controversial subject in this forum due in large part
to those who claim expertise and have nothing to show but hollow
claims (a fellow who teaches home economics in Boston). I will say
nothing further in that regard except to offer my own pages for the
eventual comparison to other sources:
http://members.home.net/kb7qhc/
contains the root page to all my antenna designs and models, and:
http://members.home.net/kb7qhc/antenna/fractal/index.htm
contains the fractal subject material you might find interesting.

Those links lead to several hundred pages of data and display. By and
large they present data and the analysis (implied) is found in the
grouping of models, I make very few judgement calls with explicit
editorialization because I prefer to trust your ability to read data
and form your own opinion. There are notable exceptions of course
that revolve around specious claims - but negative examples won't help
you right now.

Now for the serious news about fractals:
1. They are not new;
2. they are not very special (in a practical sense);
3. they are incredibly complex to implement;
4. they are neither the unique
5. nor are they the best solution;
6. they reveal no new physics of electromagnetism;

1. There are long established antennas such as the spiral or the log
periodic dipole that fully qualify in every respect (definition) for
fractal antenna design. For more than 50 years, it has been
understood that a design that is self similar exhibits tendencies for
broadbandedness. This is simply a non-optimized shorthand for design.

2. Aside from the examples in 1. (which also reveal their general
impracticality), the application of fractal patterns is more a

conceit of the designer than a engineering necessity. Last summer, papers published and presented on this subject by one of our correspondents here demonstrated that there were many arbitrary and capricious geometries that easily eclipsed standard fractal designs.

3. It should be obvious to the most casual observer that fractal designs are driven by and large by a most complex geometry if one goes beyond the second iteration (or even goes TO the second iteration). My pages reveal many such patterns. The practical implementation of these patterns is best left at scales offered in the UHF and above. [This being an amateur radio based newsgroup, we are interested in HF designs where fractals become nearly impossible to implement in all but the highest frequencies.]

4. As stated, there are many designs that are simple deconstructions of "standard" fractals that do just as well (and sometimes better).

5. Fractals are often lashed up through the shorthand of an iterated form. These examples are far from optimal. In fact my pages vividly display wild variations of design characteristics in simply comparing one fractal to another (much less a conventional antenna design). The single greatest defect in the "science" of fractal design is the dirty fact that all such examples have been discovered, not designed, and certainly not anticipated through formularies or standard methods.

6. By extension of this embarrassing defect, there follows a small community of scholars who now apologize for these shortfalls by speculating that an understanding of "fractal electromagnetics" is required to straighten out this paradox. That approach to science was abandoned to Pons and Fleishman years ago.

Let us know how your thesis is progressing.

There's an export issue. NEC-4 can't be sent outside the U.S. or used by any other than a U.S. citizen. There are rare exceptions, where application is done through diplomatic channels.

Interesting calculations. Thanks.

But how do they avoid problems with the radios on "professional"
installations (police cars, comm vans, etc)?I've seen comm vans just loaded
with antennas.
I even notice that when I transmit on 2M from my trunk mounted antenna (50
watts) it will often "blank out" my scanner on VHF, which has its antenna
mounted a couple feet away on the roof. I worry about it, but there isn't
much I can do, aside from moving my scanner antenna a little more forward on
the roof.

It is a commonly held belief that ordinary two conductor, figure 8, AC power cable has a Zo of close to 75 ohms, and an acceptable loss at HF, and is well suited to feeding a dipole.

I have measured such cables available on the market here in Oz.

When we used imperial measurements, the conductors were 23/0.0076 and the cable rated at 240VAC for 7.5A.

The "equivalent" metric cable is 0.75sqmm, 24/0.2 (rated at 7.5A) and has an effective copper diameter of about 1mm (0.04") spaced at 2.7mm (0.106") centre to centre. In an air dielectric configuration, that would have a calculated Zo of around 200 ohms. Solid dielectric will reduce this number, and my measurements on practical cables indicates Zo around 160 ohms which seems consistent with the theoretical open wire value and the likely reduction due to the limited amount of solid dielectric in the cables.

Whilst I have used these cables as tranmission lines with fair success, I don't fool myself into thinking that they are flat on a near 70 ohm load, and probably no better suited than feeding a dipole with 50 ohm coax with a balun (although lower in mass).

Theoretical loss of such an air dielectric line is about 1.3dB/100m at 14MHz, practical cables will be worse due to the PVC dielectric. If you are going to operate a "tuned line", why not just use TV ribbon or ladder line, they will have better loss figures.

Am I right in thinking that the limiting case of an air dielectric, two parrallel round conductor line is that Zo approaches 83 ohms as the conductors approach touching. Strikes me that the geometry required for a practical 75 ohm twin line would require the conductors with spacing very small compared to their diameter, and bulk dielectric with high dielectric constant.

So, is the commonly held belief that ordinary two conductor, figure 8, AC power cable has a Zo of close to 75 ohms, and an acceptable loss at HF based on a myth?

Owen

Owen,

The formula for the impedance of 2 round parallel conductors is:
Z = (120 / sqrt(Er)) * ln (2 * S / d) which yields approx.
83 ohms if the relative permittivity is equal to 1 (free space)
and the conductors are on the verge of touching each other.
However for most wire insulation materials, Er is more likely to be
in the range of 2.5 to 4.5. This would yield minimum characteristic
impedances of 40 to 53 ohms for nearly touching wires. Assuming a
more reasonable design having the wires spaced .8 diameters apart
and Er = 3.5 would yield a characteristic impedance of
120/(sqrt(3.5))*ln(2*1.6) = 74.5 ohms. Hopefully I have not made any
math errors.

Hi Will,

You are looking for Amphenol 75 ohm 1KW "TwinLine" Amphenol type 214
023.

I am using it to feed a 40 meter dipole that I use on 40 athru 10
meters center fed. I bought it in 1960 --- still good.

Very good product. Unfortunately, Amphenol is now a multi-national
organization with many divisions.

You would have a tough time finding anyone there, that even remotely
remembers this product.

Prior to my purchase, I used #18 bellwire cut to length and with one
of those old hand drills ran a "Twisted" pair with approximately 16
turns per foot.

Unfortunately, using the 40 meter dipole with this type of
transmission line (Twisted pair), I never had the opportunity to
acquire a 1kw amp. So I wouldn't recommend using more than 150 watts
with this line.

If you find a source for the Amphenol 214 023, or any other mfgr, I
also would be very interested.

73,

Rich

It will work fine. Just try top keep the angle between the legs 90
degrees or higher. I've used plenty of horizontal Vees. If the angle
is higher than 90 degrees, you'll hardly tell the difference between a
normal vee in most cases. As in most other cases, the height will have
a greater effect overall on how well it works. MK

59. VX-5R Antenna selection

I just ordered a VX-5R and I've only seen a couple of multi-band HT
antennas for the VX-5R. Each show moderate gain on VHF and/or UHF.
Does anyone have shining reports of one over another or considerations for
mobile/portable antenna setup? I appreciate any brainstorming you've got
(i.e. gotta have gain on 144 & 440, forget 6m w/HT antenna, stick with the
stock ant. and get a handheld yagi, etc).

Looks ok to me. I think we agree!

The figure 8 flex to which I referred is insulated with PVC, so a E of 3.0 is probably about right, and my calcs on the 24/0.2 (mm) conductors spaced 2.7mm yielded 200 ohms with air dielectric. Fully immersed in PVC, Zo might be as low as 140 ohms, but the PVC insulation is more like a constant radial thickness of about 1mm over the conductors, and although it is present where the field strength is highest, the lack of 100% immersion in PVC makes me think that the Zo will be somewhere between 140 and 200 ohms. Measure values around 160 ohms are pretty consistent with that.

This is the type of stuff that folk lore would have one believe is close to 75 ohms!

Having never seen a 75 ohm twinline that was measured at 75 ohms, I can only visualise that the cable needs to be two conductors of very close relative spacing, served well with solid dielectric, preferably with high E insulation.

==========
There are old stocks lying around somewhere. I wish you luck with your search.

But, as someone else has pointed out, twin, domestic, what used to be called, 5 or 10-amp, lighting cable, is usable for your application.

If you strip off the outer pvc sheath (just to save weight) you have a pair of insulated wires touching each other. These two wires at HF have an impedance of roughly 135 ohms (I have measured it). Give them a slight twist so that they remain in contact and you still have a 135-ohm feedline.

Leave on the sheath and you have a 130-ohm but heavier line.

If the insulation on the individual wires is polyethylene, as it often is, then you have really low loss line at the lower HF frequencies, say 7 MHz and below.

Use these lines to feed the centre of a 1/2-wave diople. There will be standing waves on the line but of reasonable value and the loss should not be excessive. Depends on frequency.

Suck it and see.

If you need a very long line from antenna to shack then there may be no alternaive but to use 450-ohm ladder line or 600-ohm open-wire line and use a balun + tuner to match to 50-ohms at the transmiier end.

Just had a second thought - I have used twin, stranded, 18 and 20 AWG, speaker cable in the past and found it OK on 160 and 80 meters. It has an impedance of about 140 ohms regardless of wire gauge. The heavier the gauge the lower the loss.

Again, suck it and see.

Regards, Reg, G4FGQ

Owen Duffy wrote:
"Whilst I have used these cables as transmission lines with fair success, I don`t fool myself into thinking they are flat on a near to 70-ohm load----."

Probably not. Spacing between the wires doesn`t change as rapidly as wire diameter so larger cables have in general lower impedance than lower amperage cables which use smaller wire.

Owen gave the characteristics typical of the extension cable used in "Oz". Outlets in the U.S. are rated at 15 amps, typically. A house wired in open air can carry 20 amps with AWG-14 wire, or 15 amps with the same wire in a raceway. AWG 14 is often used for house wiring. The electrical convenience outlets are typically rated at 15 amps so it is fairly common to use extension cords also rated near 15 amps.

Owen found the diameter of his figure-8 extension cord to have wires of about 1mm diameter (0.04 in) spaced at 2.7 mm (0.106 in), center to center. In the U.S., that wire size is AWG-18, which is quite commonly used for extension cords in the U.S. too. We also use a lot of extension cords with AWG-16 wire which is .0508-in dia. and can carry more current.but is still smaller than the permanent wiring.

With larger diameter wire and almost the same distance between wires, and considering the dielectric constant of the plastic insulation, it is likely that heavy zipcord comes closer to 70-ohms than Owen`s sample did. I haven`t measured the surge impedance, but would expect to find some examples that were not too far from 70 ohms and reasonably low in loss at moderate frequencies.

Best regards, Richard Harrison, KB5WZI

63. Diamond Antenna RH77CA and RH3.

Source record: 156717

I picked up a 4BTV used a couple of weeks ago (for $60 good deal as it was only 3 months old) and have had good luck with it once I got it adjusted for each band. It helps to have access to an antenna analyzer. It definitely gets out OK. I can't have permanently mounted exterior antennas where I live, but wanted something other than my attic dipoles. I pounded a four foot piece of galvanized 1 1/4 inch pipe about 2 feet into the ground and mount the antenna on that. I use 8 radials clipped to then antenna mount and laying on top of the ground. SWR is 1.2 at 28.000, 1.5 at 28.300 and 1.7 at 28.600. On 15 meters SWR is 1.8 at 21.000, 1.3 at 21.200 and 1.3 at 21.450. On 20 it is 1.2 at 14.000, 1.3 at 14.150 and 1.8 at 14.350. The internal tuner on the Icom 746 matches it well. Hears well and gets out well considering the limited installation. It's light enough I can put it up and take it down by myself to keep the homeowners association happy. 40 meters is not as broad banded, but the internal tuner matches it just fine. Another inexpensive antenna I have have had good luck with is the Solarcon Imax 2000. SWR on 10M is about 1.3, it is 2.0 on 12M and 1.2 on 15M. I have it mounted on a piece of pipe in a 5 gallon bucket of cement. Also easy to put up when I need it. I worked some great
DX already with the Solarcon. Hope the info helps. Ken, Nï¿½VZ

This thread has led me to wonder about some surplus twisted cable wire I once had. It was 4 conductor and teflon coated. Conductors were stranded, about #16 IIRC.
I'm thinking that a pair of these wires, untwisted from the rest of course, might have made a somewhat decent transmission line close to 75 or 100 ohms, with reasonably good RF characteristics. I must have gotten rid of that 1000 foot roll (because it is no longer here and was too hard to strip anyway :-}.
Has anybody tried any teflon coated wire twisted pair like this as a xmsn line?

You could get the effective surge impedance down to half as much by using
two of these 135 (or 130) ohm lines, of equal length, connected in
parallel between load and source, but spaced reasonably apart except right
at the ends. I would think that the voltages involved would be low enough
that wood, or light plastic, spacers to hold the two lines apart would be
good enough, barring operation under high SWR (such as using an 80 metre
half-wave dipole on 40 metres).

Be careful in connecting the two lines. There are two ways to do it, and
if you think about it you'll see that one way will result in a dead short
at the source end (except for the fact that the lines will have loss). If
the wires are color-coded it will be easy to do it right; otherwise haul
out the ohm-meter first.

Agreed!

AWG-16 (.0508" / 1.29mm) spaced at 2.7 mm (0.106 in), center to center
in air is 171 ohms, fully immersed in PVC is 99 ohms. Practical cable is
probably somewhere 115 - 145 ohms depending on the coverage of the
dielectric.

I'm in the market to upgrade my six meter antenna from a dipole to a 3 element beam. I've looked at a couple designs by a couple different manufacturers.

MFJ-1762 - Looks good, reasonable price, I can't get MFJ to contact me about the shipping charge. Anybody know it?

A503S - By Cushcraft, little more expensive than others, better construction (?)

Does anyone have any experience with these antennas, or anything similar? Thanks for any help.

Go to www.eznec.com, download the demo version and model your antenna.

Or, get a dozen opinions; here's mine without doing the simulation - it
will be directional. How directional depends on the angles.

Matthew Delaney wrote:
"But how do they avoid problems with the radios on "professional"
installations (police cars, comm vans, etc)?"

A little distance is provided between antennas. It makes a big
difference. The near field drops much more rapidly with distance than
does the radiation field. A few wavelengths and the near field, which is
strong in the neighborhood of the antenna, is of no significance. The
radiation field at 10X the distance from the antenna is only 1/10 the
volts per meter as it is at the closer distance. Just the distance from
front to rear of the passenger compartment in a car is nearly always
enough antenna separation to avoid damage to a receiver of one waveband
from a transmitter of another. If vehicles continue to shrink, this may
not always be so. One foot separation is a small fraction of a 2-mtr
wavelength, so the coupling is just excessive.

Best regards, Richard Harrison, KB5WZI

Jim- I have the MFJ unit, and have been happy with it. It has been through one winter, including one "Ice Storm". This is a phenomenon of the mid-US, where the temperature stays within a degree or two of freezing for days, with high humidity. The result is that conifers, like Pines, and wires, like power lines and dipoles, and antennas, like tribanders and other Yagis, get a progressively thick coat of Ice. In my case, the tribander survived (thanks, CushCraft), the dipoles sagged to the trees, and the MFJ 6M had a peculiar thing happen. The Ice load was right at the marginal point, and made a slight permanent set droop to the reflector, while the driven element and the director (both are shorter) straightened back up,when the Ice melted. Really, it survived a HEAVY load with only slight (humorous) physical change, I can see no change electrically.

I think the MFJ 6M Yagi is a very good buy. I am happy with mine, and, if the next Ice storm does REAL damage, I will probably get another.

Look up Collinear antennas. Thats what many people use a 6 or more db collinear antenna. You can make it out of stacked half wavelength of coax pieces. There is some info and projects in AC6V.com webpage under antenna projects.

In many other countries they sell collinear antennas for people in rural areas and they work well. But in my opinion if you dont feed it with at least LDF450 or better you waisting your time. The losses in crap coax will negate the gains of the antenna.

Good Luck

I have been using the KMA5054 from KMA Antennas. It's very rugged and
will also work on 2 meters. It covers both bands with swr less than
1.5. It is the biggest bang for the buck that I've seen.

You, nor anyone else, will not notice any difference from a
half-wave dipole at about the same average height. Don't waste time
wating for replies from newsgroups. Just get yourself loaded up and
away you go.

Happy DX hunting !

That seems a little unfair. The claim Fractus makes (far more lucidly
than claims I've heard from others) is that (some?) fractals can keep a
directional pattern clean at frequencies higher than the fundamental
resonance, without forming additional lobes and nulls. You would have
difficulty doing this with a directional antenna built from a single
wire. Avoiding nulls in the antenna's pattern is particularly important
for cell phone base station antennas, so there is utility if it works this
way.

I don't know that this is true, but I know of no reason to doubt it.
If an LPDA can accomplish this then other fractal arrangements might
be able to as well.

Thanks to all that helped.. Here is what I did:
I was unable to get the center out of a SO-239 panel mount connector, so I used part of a crimp connector from a Radio Shack "bulk" modular plastic connector. I pulled the pin out of a PL-259 and replaced it with the crimp. Then I took some 12ga solid wire and fit it in half the crimp and slide it down the PL-259 barrel and crimped the top of the PL-259 over it. When I screw it down the mag mount base, the other half of the crimp fits over the center pin on the base. Haven't road tested it yet, but it worked nicely in my driveway. (Under 2.0:1 across the 2M band)

>or the
>HUSTLER 5-BTV 80-10m Vertical Ant

had mine (5-BTV) for 12 years on the roof. One day the SWR was down,
so I decided to buy another antenna. After taking it down from the
roof, I realized that only the screws fell off, becose of corrosion.
So, at the end, the 5-BTV was still perfect in shape, just did not
have the right height. A very strong and sturdy antenna!

If it's used on the low bands at fairly low heights, the pattern will
be fairly undirectional. I've used loads of those on 40 and 80 meters
and the difference from a straight dipole is fairly small. Actually,
the gain is less than a straight dipole. "2.1 dbi". With a "L" dipole,
you still have some broadside gain, but it's less than a straight
dipole. So normally you shouldn't see much in directivity in the
average setup. "Say a 40m L dipole at 40 ft". The dipoles work very
well in an L configuration. MK

83. Help feeding 2 antennas

Hello all,

I am trying to feed 2 different antennas on 7Mhz, one is a dipole the second is a 1/4 wave vertical, both antennas were cut and tuned for 7Mhz only. What I would like to do, is transmit on both antennas in same time, and select one of the 2 antennas for receive.

What do you think about this.
Also how should I feed this antennas for transmit to keep a good match?

Thanks.

What are the good antenna tuners out there rated for high power? I have an MFJ 986 that is supposed to be rated for 3kw PEP input but MFJ tells me it is only good for about 400 PEP on 160 and not much more on 80 meters--using a ladder line fed dipole. Go figure. They don't advertise that! My other high band antennas are all coax fed and have pretty good 2:1 band width, so a flat liner is all that is needed there. Amp is an AL-1200 that will cruise all day at about 1200 watts.

How is the Nye Viking, the Amertron and some of the other tuners at handling a 1000 watts or more on a 450 ohm ladder line fed antenna?

If that was his claim at least it can be researched and either proved or disproved by others. Somehow he was incapable of writing it up into even a small text file to replay to inquirers. He instead insisted on labeling everyone who asked any question whatever as his detractors. We had no idea what to detract.

Hi Rudy:

You want a stout tuner? Try a Palstar AT4K (if you can afford it). I have one of these that I bought several months ago and most likely will keep it for the rest of my life. I almost bought a Nye Viking til a friend recommended this tuner and once I got it, I never looked back. As far as I am concerned this is the best tuner on the market....Period.
I can run legal limit throught this tuner without it flinching a bit using my QRO HF3KDX. I have also heard that DXers in other countries(with higher power limits) have pumped even more power into these tuners without any problems. The thing even has a cooling fan for the roller
inductor. They use the highest quality components and the workmanship is excellent.

Here is the Palstar website
http://www.palstarinc.com

Here is the AT4K tuner
http://www.palstarinc.com/at4k.htm

Want to find out what other owners say about this tuner?
http://www.eham.net/reviews/detail/809?ehamsid=79f27b97075686d2ee998d48eb513936

You can also compare this tuner with other tuners:
http://www.eham.net/reviews/products/3?ehamsid=79f27b97075686d2ee998d48eb513936

This tuner might be overkill for your needs but then on the other hand.....
I hope I didn't complicate your wish list. This item will definitly lighten your wallet!
;-)

From: Per Enocson <per.enocson@telia.com>
Message-ID: <XEHu7.5460$aM.541278@newsc.telia.net>
Source record: 156650

I have a 32 ft ground plane antenna on the roof of my house with six 32 ft radials. I works fine on 40 m and I believe I could use it as a 5/8 ground plane on 18 MHz as well.
From tha ARRL Antenna Book I get the impression that radials for a 5/8 antenna should be shorter than 1/4 of a wavelength, but there is no explanation on how to calculate radial length for a 5/8 ground plane. The feedline is currently 50 ohm coax.

Anyone out there who knows and can help?

Thanks, 73's de Per / SM0WRA

Hi Dennis,

You are right, it was a bit heavy handed. However, every one of my designs is compared to a standard monopole over the same region of frequencies and that straight piece of wire resonates in more than one band. This is not a remarkable talent.

The painful point of fractal antennas as either a science or an engineering pursuit is that fractals are neither. To this date, absolutely no academic nor professional has disclosed ANY causal correlation between the nature of the fractal form and its antenna properties.

As for our home-ec teachers's claims. I won't dismiss them, they are
in all likelihood accurate - to the specific point. All too often
those same claims were dressed in another argument's cloak.

Let's consider:
>The claim Fractus makes (far more lucidly
>than claims I've heard from others) is that (some?) fractals can keep a
>directional pattern clean at frequencies higher than the fundamental
>resonance, without forming additional lobes and nulls.
There are more than 100 elevation profiles located at:
http://members.home.net/kb7qhc/antenna/fractal/Constant%20Height%20Comparisons.htm
simply click on any gain figure in either table for any fractal design
at any frequency. I am sure there are MANY there that conform to the
specification - and many that do not - all fractals.

The fact of the matter is the claim that you picked up on is a data
point, not information. I seriously doubt its substance within the
context you heard it.

And back to the patterns. I have seen thousands. The data I have
presented to this group and published on the net is only that much
that can be offered coherently. I can almost assure you if you took
any of the EZNEC models I offer, and swept them in frequency; then you
would observe the most convoluted 3D beam stearing you could have
imagined. In service as an LPDA, these are the most abyssmal
replacements I could imagine.

99. New L-Match Design Program

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-03 18:24:50 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9pfml7qed1@neptunium.btinternet.com>
Source record: 156652

IMPEDANCE MATCHING WITH L-NETWORKS

The simple L&C L-network is capable of matching any pair of complex impedances to each other and, when used in RF power applications, it always has a lower internal loss than any equivalent T or Pi network using the same quality components.

Its disadvantages are that to cover a full range of impedances it is necessary to switch the circuit locations of L & C and/or change the direction of transmission. This means neither component can have a permanent ground connection.

Also, at the lower radio frequencies inconveniently large values of capacitance are sometimes needed. (T and Pi networks are popular because they can be designed to avoid these two disadvantages.)

But as the L-network has only two components and circuit changes can be quickly accomplished using alligator clips, it lends itself to simple homebrewing, wind-your-own coils, etc.

A new program L_TUNER is now available from website below.

For a given terminating impedance R+jX and frequency, and the required network input impedance (which may also be complex), L_TUNER computes component L & C values and offers a choice of network configuration.

Input to the program, R+jX, can be obtained sufficiently accurately with a modern hand-held antenna analyser. The program will be useful designing networks to match coaxial lines to the peculiar impedances found at the base of vertical antennas. Use program SOLNOID2 to design coils.

L-networks are used in other places such as amplifier outputs and interstage couplings. They tend to have wider bandwidths than other types of Z-match circuits.

Download program L_TUNER in a few seconds. One self-contained file of 39 Kilobytes. Simplicity itself to use.

Source record: 156654

I made some measurements today on 18 A.W.G. vinyl insulated zip cord.

I used a HP 250 RX meter and followed the method described in the instruction manual, Z0 measured with a 1/4 wave section and loss measured with a 1/2 wave section. As recommended in the manual, I first constructed a 4:1 balun using RG58, since the 250RX meter is an unbalanced instrument.

The sample of zip that I measured has two No. 18 AWG conductors. I measured these as 0.048 inches diameter with a micrometer, which matches the spec for 18 AWG. The center-to-center spacing is 0.108 inches. For those not using our quaint measuring system, the wire diameter is 1.2 mm and the spacing is 2.7 mm.

I measured the capacitance as 23.0 pF/foot (75.4 pF/m). Measuring the inductance is tough and is discussed later.

Based upon the length of RG58 that I had available to make the balun, my measurements were made at 19.3 MHz.

I measured Z0 = 75.9 ohms. So far, so good. The attenuation, however, is crummy. I measured 21.2 dB/100 ft. The vinyl insulation used in zip cord is apparently selected for flexibility and price, not its RF performance! Presumably, at a lower frequency the loss might be tolerable, at least for a short run.

The velocity factor I measured is 0.64. A 1/4 wave section at 19.3 MHz is 97.3 inches (2.47 meters) in length.

Since Z = Sqrt(L/C) the L for 97.3 inches should be around 1.07 uH according to my calculations. We need to measure this at a sufficiently low frequency that we can ignore the transmission line effects. None of my RLC bridges will accurately read this low a value at 1 KHz, so I used my HP 4342A Q meter with an auxiliary capacitor. With a 0.47 uF cap, I measured 1.62 uH at 182 KHz.

I have a CD44 rotor and the CDE control box for sale.
The rotor rotates 30 degrees one way and then stops. It rotates back to the original position.

The face of the box (glass and front face) is excellent; the top of the control box has a scratched area the size of a quarter. This is the box with three levers.

The rotor has two plastic rings that hold bearings; those rings are not solid pieces (if they are supposed to be). Each plastic ring (upper and lower) has one break and seems to be missing a few bearings.

Would like to get 75.00 plus shipping from Greenville, SC, but will talk.

Jack, firstly congratulations on doing the measurements to add some
practical data to the discussion.

I calculate the Zo of an air dielectric line of D/d=0.108/0.048 as 180
ohms. Am I correct in thinking that to achieve 76 ohms would require a
dielectric of pemittivity (180/76)**2 or 5.6. An even higher value of E
would probably be required as it is unlikely that all of the field is
effectively contained within the vinyl insulation.

Is a relative perittivity of 6 or more likely for such insulation -
seems high?

>
> The velocity factor I measured is 0.64. A 1/4 wave section at 19.3
> MHz is 97.3 inches (2.47 meters) in length.

Isn't velocity factor related to E (VF=100/E**0.5), so a velocity factor
of 0.64 indicates E is effectively 2.4.

The Zo measurement and VF measurement seem inconsistent for that line geometry to me.

Has anyone an explanation?

Rudy,

I have the Nye-Viking MB-5-A. This tuner will handle most anything
that I throw at it. I have not tried it on 160 yet, as I have no antenna
big enough for that band, but the Nye handles the 1.5k into a ladder
line fed antenna on 80 meters. I use my amp, a TL-922, all the time
and this tuner can take it.

The Palstar is reportedly a good tuner also, but having no personal
experience with that one, I can't say anything.

I can endorse the good old Nye-Viking though!

Owen:

I agree that something is strange with the data.

I dug back into my old lab notebook and found that I had made this measurement before, on 28 December 1997 but using my GR916 RF bridge, not the RX205A. The zip cord I used then was similar, but but not from the same reel.

The data that I took then used a pair of T80-2 ferrite cores as a choke balun, and I used the Zo = Sqrt (Zsc*Zoc) method with a length of cable of 22 feet. This data showed Zoc = 36-j87.5, Zsc = 26+j175. Converting to polar form and computing Zo yielded 129.4 @ 6.95 degrees. Without a balun, Zo was around 118 ohms.

I was able to measure the L at 1000 Hz then, using my HP4260A bridge and found it to be about 5.1 uH. The C was 20.6 pf/ft which yields a calculated Zo of 104.8 ohms. I would not bet the mortgage money on the L measurement, as it's at the extreme limit of instrument range.

On 29 Dec 1997, I used my HP 8754A network analyizer and determined that Vf = 0.59. Here I terminated the zip cord in a 50 ohm termination and then determined the frequency at which the network analyzer saw 50 ohms. That should have been a multiple of 1/2 wave. I used a ferrite rod as a choke balun for these measurements.

As a check on my methodology in 1997, I also checked a 97 inch length of commercial 300 ohm TV twinlead. Using the GR 916 bridge, I calculated Z0 = 261.6 ohms. (Using the ferrite choke as a balun.) at 5 MHz. Measuring without a balun yielded 284 ohms.

That older data is quite a bit different from what I took today. I'll recheck my math and remeasure tomorrow and also remeasure the zip cord with a couple different techniques. It was pretty clear today that stray C is a bit of a problem, but I didn't think it was enough to throw off the data by the degree it appears to be off. HP recommends running the measured balanced line vertically away from the RX bridge, so I'll see if that helps.

In 1997, I had also had taken a look at a piece of RG-58C and found Zo = 49.1 ohms, so that gives me confidence that the overall methodology worked then, at least with the GR916 bridge. The data I took today is the first time I've tried using a coaxial cable balun and the problem may reside there.

Whoops, I wasn't talking about him. I've never heard him claim this
that I can recall.

>The fact of the matter is the claim that you picked up on is a data
>point, not information. I seriously doubt its substance within the
>context you heard it.

Do you mean these?

C. Puente, R. Pous, "Fractal Design of Multiband and Low Side-Lobe
Arrays", IEEE Transactions on Antennas and Propagation, vol. 44, no. 5,
pp. 730-739, May 1996.

C. Puente, J. Romeu, R. Pous, A. Cardama, "On the Behavior of the
Sierpinski Multiband Fractal Antenna", IEEE Trans. on Antennas &
Propagation, vol. 46, no. 4, pp. 517-524, April 1998.

I have no idea whether you'd classify these as "data points" or
"information", but I don't think they're entirely without substance
and the results made sense to me. It intuitively seems that an antenna
which keeps its pattern at several frequencies (without changing its
electical shape with traps) might need to be geometrically self-similar

at several scales, and there is at least a bit of science to support this. That you can find no merit in Boston doesn't necessarily mean there is no merit in the field at all.

Yes, if the spacing and diameter are as you say, a line with VF = 0.64 should have a Z0 of 111 ohms. To get a Z0 of 76 ohms with this diameter and spacing would require a velocity factor of 0.44, so the measurements aren't consistent.

Be careful when using the log-based formula. A lot of people don't realize it's only an approximation, and it becomes increasingly inaccurate as the two conductors get closer together. The correct formula is Z0 = 120*arccosh(D/d) where D is the center-center spacing, d the diameter, and arccosh the inverse hyperbolic cosine function. With this formula you can see that the impedance approaches zero as the wires get extremely close together (D/d -> 1).

As for wire insulating materials, you have to keep in mind that the effective Er is less than the Er of the material unless the entire field is immersed in the the material (as it is in coax). With twinlead, part of the field is in air and part in the dielectric, so the effective Er, used for impedance and velocity factor calculations, will always be less than the Er of the material. Just how much less depends on what proportion of the field is in the air vs being in the material. Incidentally, with twinlead, microstrip, and similar structures, the air-dielectric distribution of the field changes with frequency, leading to a change in Er and therefore propagation velocity (and Z0) with frequency. This is sometimes a dominant cause of dispersion.

That seems unrealistically low. I wouldn't expect it to be significantly better than coax of the same characteristic impedance, and with a somewhat smaller conductor, and comparable coaxes have much more loss than this. At this impedance level, dry polyethylene (polythene) insulation won't add significant loss below UHF -- it's not significant even in coax, where the whole field is in the dielectric. PVC might well be nasty enough to show up, though.

No. I just made another posting explaining why.

> So, is the commonly held belief that ordinary two conductor, figure 8,
> AC power cable has a Zo of close to 75 ohms, and an acceptable loss at

It probably isn't far from 75 ohms. And "acceptable" is something that varies a huge amount from person to person and situation to situation. I'm sure quite a number of people eat 20 dB of loss and are plenty happy with how many stations they can talk to with a 100 watt rig. You can make a loot of QSOs with one watt. See, for example, past threads on the B&W wideband antenna.

Hi Dennis,

If you would consider the breadth and depth of coverage I provide, I
doubt you would come to the conclusion that I dismiss this field as
having no merit.

I understand now that you were speaking of Puente, et. al., still and
all, the claims I see even from these foreign shores does not
materially change my criticism. And yes, all such claims are
natterings of discovery not of profound insight.
> It intuitively seems that an antenna
>which keeps its pattern at several frequencies (without changing its

>at several scales, and there is at least a bit of science to support
>this.
There is in fact very little science - as you describe it here. And
as you have described it, I have offered counter-examples by the
score.

Saying you hold a fractal that exhibits such-and-such qualities does
not mean that all (or most - or even some) fractals exhibit those same
qualities. Can Puente teach us how to find the major lobe of the
second iteration of ANY fractal at ANY frequency? ANY subset of
fractals (and not leaning on existing LPDAs and such)?

Can Puente, et al., teach us what the feedpoint Z will be for ANY
fractal at ANY frequency? When I say ANY, this is to mean I fully
expect he or others can trot out their mascot and jump it through
hoops; what I want to know is can they teach other dogs the same
tricks? - I sometimes wonder if it's the dogs that have their
masters trained.

I had hoped Barry Ornitz would have weighed in here with his encyclopedic knowledge of plastics. Few AC power cords are manufactured with polyethylene insulation, for one thing it has too low a melting point. The polyvinylchloride (PVC) insulation usually used these days (rubber is still available) varies all over the map in dielectric constant and RF loss due to the plasticizer used to make it flexible and the pigments used to color it. I would be interested in the results of measurements on some of the "monster" speaker cable which uses clear PVC insulation, and has 10 or 12 ga. conductors.

Hey, and being made with "oxygen-free" copper, its use as RF line should result in much better quality signals.

Just because the SWR is low doesn't mean that the antenna performs
well. Remember that a dummy load has a low SWR on all bands. If you
really want a measure of antenna performance, try efficiency
(radiation resistance divided by feedpoint resistance) or field
strength meter trials.

Remember: Kurt Sterba warns his readers about "low SWR for the wrong
reason". On my website, I have uploaded a document called "When Low
SWR Is Bad" that illustrates examples of antennas that have higher
SWRs AND higher performance.

hello
i have just upgraded to general and i am looking for a good HF multi
band vertical
that does NOT require ground radials and must be under $200 the ones i
am looking at are the hustler 5-BTV or the MFJ 1796
i know the MFJ doesnt need a ground but not sure of the hustler so what
i need to know is which of the current vericals on the market would fit
my needs and that actually perform well for what they are i dont want to
spend $200 on a bunch of aluminum and all i have is a big dummy load
so all you vertical users tell me your opinions
thanks

Well, it must work OK because I have logged the following DX working
barefoot this week:

E. Kiribati, Papua New Guinea, Conway Reef, Morocco, Kuwait, Panama,
Siberia and a bunch of more mundane DX stations. It's no beam, but if
you can't have a big antenna it works very well. Ken, N0VZ

jason
as you have found there is no one right answer
i think i was the one who told you the 9.6 feet thats what cushcraft
suggests to use on there 7 ele 2 meter yagis
ideally what you want to do is take the beam pattern of the E plane or
Hplane depending on how you want it stacked and the polarity of the antenna
the Eplane is for the yagi being horizontally polarized and the Hplane for
vertical ant stack them just slightly smaller than that figer to get the
gain you want but if they are homebrewed antennas you will not have that
data availible so you will just have to make due its not that big a deal get
you a piece of pipe 10 feet long and 1 1/2 inch in dia and mount the
antennas on either end first at 9.6 feet and try it by checking distant
signals and make sure there is not a null in the middle of the pattern if
there is you know you have them to far apart then slide then together a few
inches and try it again it took me many tries with my 4 11 ele yagis before
i got the spacing right
after all this is a hobby and you wont learn anyhting with out experimenting

good luck
and by an amp they are cheap 2 watts in with 50 watts out is under $100

127. Re: 75-Ohm twin-lead: still available?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-04 06:00:03 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9pgu5o$no3$1@neptunium.btinternet.com>
Source record: 156580

For Ro = 75 ohms the spacing between centres of an air-spaced line
is only 1.2 times the wire diameter. So for 1mm, 18 AWG wire the
space between wires is only 0.2mm = 0.008 inches.

The HF attenuation of such a line is MUCH, MUCH greater than 75-ohm
coax with an inner conductor of the same wire diameter because of
the proximity effect. Nearly all the current is concentrated on
the close facing surfaces of the wires.

When embedded in plastic the 75-ohm twin line has its wires a
little further apart but the loss is still greater than coax having
the same gauge wire.

That's probably why 50-ohm HF twin line has never been made. It's
an attenuator.

You can use almost anything I guess. Many use 1/4 wave radials. I've
tried 3/4 wave radials, which seemed to me better than 1/4 wave
radials. I've use the same antenna as you want to use, and I used
34-36 ft radials, which also worked on 40m. I usually trimmed the
radials to have a good match on 40m, more than 17m. These would be
close to 3/4 wave on 17m. I've tried modeling the different types,
1/4,3/4, 5/8, and the 5/8 radials give the most gain, but in order to
have this gain you needed a pretty steep slope to the ground. If you
had a fairly normal 45 degree slope, the gain showed to give the
textbook 3 dbi gain. The 1/4 wave radials are the worst as far as
performance, but will work. If you have a steep 20 degree slope using
5/8 wl radials, the gain approaches that of a dual 5/8 collinear.
Maybe 1 db less, which isn't much. You might want to look at the page
where I modeled these. It's at http://web.wt.net/~nm5k/acompari.htm So
anyway I would try the radials you have now. According to modeling
,they are the best length as they are for max gain on 17m. Adjust the
match for 17m by adjusting the loading coil. I assume you will bypass
the coil for 40m. I used a 24v relay to do that. I had that antenna at
36 ft, with 4 radials. It worked great on both bands. On 40m, it was
great for dx, and also the same on 17m, where it outdid all my other
wire antennas on almost all paths. You will note a 5/8 on a car uses a
larger than 5/8 wave body/groundplane of uncertain dimensions and
still works. Actually, many times it's better on the car than if it
were over 4 1/4 wave radials. A 5/8 antenna really wants to see a 5/8
groundplane for max gain according to modeling. But then it becomes a
dual 5/8 collinear and is not a ground plane any more. MK

> k5qwg

If that was the case, the problem was excess loss somewhere rather
than the L of the antenna legs. My guess would be the tuner. Were you
careful to use the least inductance? I've got the same tuner and it's
pretty critical from tests I've done with it. Also, I've never had a
80m dipole fed with a tuner and ladder line that was equal to a
straight coax fed dipole. No matter how careful I was tuning. I've
pretty much lived on 80m most my ham life. I get every last bit of
performance I can on that band, which means I almost always use coax
fed dipoles. Now, I'm sure many will say, hummmm, how can he tell the
difference when the amount is supposably so small? It's my theory that
amount is not always small. I've A/B ed em, and coax fed wins every
time, and the difference is quite noticable usually. So I only use the
tuner for weird experimental stuff in general. You can model a
horizontal L dipole, and the pattern is barely effected overall. "I've
already tried it". Just a little less gain broadside is the only real
difference. Also I've never had trouble with one in the real world,
but all were coax fed in my cases. But I'd still rather spread the
legs apart farther than 45 degrees if possible. MK

|Hey, and being made with "oxygen-free" copper, its use as RF line should
|result in much better quality signals.

I had a guy working for me (a graduate EE) in a components engineering
department who was a pretty good guitar player and hi-fi buff. He swore that he
could hear the differences between different speaker cables. I told him he was
nuts and dug up one of Bob Pease's articles on the subject wherein he said
people that thought this were nuts too.

I guess when you have "perfect pitch" you can hear this stuff, but only if the
connections are gold plated <g>.

With Roy's correction (Zo=120arccosh(D/d)):

I calculate the Zo of an air dielectric line of D/d=0.108/0.048 as 174
ohms. Am I correct in thinking that to achieve 76 ohms would require a
dielectric of pemittivity (174/76)**2 or 5.24. An even higher value of E
would probably be required as it is unlikely that all of the field is

effectively contained within the vinyl insulation.

Is a relative perittivity of 6 or more likely for such insulation - seems high?

The Ameritron ATR-30 is excellent. It will handle more than 5KW of RF
on 160 meters and higher.

I've replaced alkl my KW Matchboxes with ATR30's. They handle more
power and match a wider range.

Beware of tuners that need an internal fan to keep components cool.

>concept of "true peak" power metering)!

Most tuner ratings are false when you consider output power.

Most of it stems from years past when ALL tuners were rated in INPUT
power to the PA, not output power. So a 2kW tuner is actually a tuner
for an old 2KW amplifier, like the Heath SB220 which was a 1200 watt
PEP and 600 watt CW output PA.

A second problem is many people just don't understand to use maximum
possible capaciatnce when loading a tuner, and many manuals don't
explain it well.

While the peak power reading in the MFJ tuners sucks, the peak power
in the ATR30 and all other Ameritron products is dead-on. I can
actually see very quick antenna arcs on my meter in the ATR30, and one
dot on CW takes it to full scale when reading peak.

That isn't true. Look at the Z match. The roller is about the size of
the MFJ roller, and the capacitors are very close spaced.

The only thing unique about the X-match is it uses a high value of C
(it is still a conventional T network), which makes losses lower on
low bands. But the ART30 will run circles around it, and even includes
a power meter and costs less.

If 100' is 20dB range, then the Return Loss would be a nearly perfect 40dB. Might make a cheap dummy load.

But wouldn't most of the power be lost in the first few feet ? If anyone were to use it for transmitting say 100 watts, the first 20 feet would eventually melt.

The antenna worked because its efficiency was respectable and band
conditions were good. The fact that the SWR was 1.3 instead of 1.9
was unlikely to have been relevant.

Hi Dennis:

Regarding the impedance and multi-band performance of the self-similar
Sierpinski gasket and self-similar fractal antennas in general, you must
consider one very significant point. In most, if not all papers or articles
published on self similar fractal antennas (or fractal antennas in general),
there is never a performance comparison with non self-similar geometries
having the same volume and same geometric compression. With the fractal
loop and monopole antennas there has never been a published performance
comparison with other bent wire loops or monopoles having the same overall
size and total wire length (excluding two papers presented at the 2000 IEEE
AP Symposium). With the Sierpinski gasket there has never been a comparison
with other "gaskets" having a multiple gap structure that may not be
self-similar in its shape or placement.

The proponents of fractal antenna designs are usually correct in the
performance characteristics they describe for the fractal antennas they
choose to analyze. However, without making any comparisons to non
self-similar or other bent wire geometries of the same overall size, total
wire length, etc, it is naive to conclude that the performance properties

are somehow a direct result of the unique fractal geometry.

For instance, Puente demonstrated that the self-similar Koch fractal monopole antenna exhibits lower resonant frequencies than a Euclidean monopole of the same height. He concluded that because the fractal has a complex, convoluted shape that is highly rough and uneven, it is more effective as a radiator. If he had bothered to compare the Koch fractal monopole to a simple meander line monopole antenna or a normal mode helix having the same height and total wire length, he would have discovered that these well known, simple shapes are more effective at lowering resonant frequency. In fact, with less total wire, these antennas can be made resonant at the same frequency as the Koch fractal. The self-similar fractal is at an inherent disadvantage over these simpler geometries because the increase in total wire length is uniquely constrained to the fractal curve. In terms of lowering resonant frequency and performance as a small antenna, the self-similar fractal antenna is one of the most ineffective designs possible.

To mitigate this issue when challenged, the fractal proponents will generally declare that all random, bent wire geometries are simply random fractals because they are self-affine, therefore, "see how well the random fractal works". If we were to agree that random geometries are simply random fractals, then we would also have to conclude that fractal antenna designs have been characterized and well understood for over 60 years and that assigning the term "fractal" to them changes nothing about the physics or our understanding of antenna performance. Increasing the total wire length in an antenna of fixed height lowers its resonant frequency. The most effective geometry at lower resonant frequency is generally the one occupying the most physical volume. For a given wire length and fixed height, the spherical helix is perhaps the most effective linear wire antenna for lowering resonant frequency.

While the self-similar fractal has an inherent disadvantage in terms of lowering resonant frequency, it has a significant advantage regarding the antenna's multiband performance at high frequencies. While I need to do a bit more work, it is my opinion that the high (or tight) wire compression, not the self-similar geometry in and of itself, is more a factor in the multiband performance of the antenna. Comparing the performance of the self-similar geometry with other highly compressed geometries that are not self-similar, I have found that they exhibit almost identical multi-band performance at high frequencies.

Hello,
I have been experimenting with my radio as of late (since I upgraded to general) I have a tuner and some radom wire. I have been trying a 25-30 foot piece and about an 8 foot piece (that I never get fully unrolled). Living in an apartment with not a lot of space to put anything outside. (I have a little balcony I have been using to toss the wire out on).

I have been making contacts with the 80 foot piece even tho I have some of it rolledup on the spool. How bad does this hurt me?

I was looking at verticles to put on my balcony. Will they work any better than the random wire and tuner? If so how much? I was looking at an outbacker (This is why I ask, as they are a tad expensive)

Any input would be great.

Thanks
-Ryan

Don't recall whether I used least inductance, but I always tuned the inductor for the loudest received signal, and went from there to get the transmitted signal showing the least amount of reflected power. I could get the swr pretty much down, but no one could hear my 100 watts.

(This was back when they shipped the the 989c with absolutely no tuning instructions, other than a little 4-pager on setting it up. Since then, I've downloaded much better instructions from their web site.)

Roy,

You are amazing. Your formula certainly explains away the major
discrepancy. For what it is worth:

Approx. formula Z = (120/Er)*ln(2D/d)
Exact formula Z = (120/Er)*arccosh(D/d) but
arccosh(x) = ln(x + sqrt(x*x - 1))
As x gets larger x + sqrt(x*x - 1) approaches 2x
and the formulas become the same.

Thanks for the info.

Hi Dennis,

I've been going down the same path just a tad ahead of you. One thing I've learned is that there aint no free lunch. I bought (arguably) the best -a Butternut- and am still adding radials and tuning on it. It's supposed to work on 80-10 meters, and it does, but the SWR is so high on some freq's that I still have to use an tuner to keep my rig from going QRP in self defense. If I had it to do again, I'd buy $40 worth of aluminum tube* and make my own vertical, about like the catamaran mounted one in the current QST, and put a tuner (automatic when the $$$ appear) at the base of it. If you ground (vs roof) mount it you *might* get along sans radials provided you water your lawn a lot ;o). Good luck & remember, getting ther's half the fun.

This is a difficult problem to solve in the general case. For the optimum case, where both antennas are perfectly pure 50 ohm feedpoint impedance, this 50 ohms can be transformed to 100 ohms with a quarter wave line of 75 ohm coax, and then the two 100 ohm points can be connected in parallel to produce a 50 ohm load.

Another possible approach is to connect two power meters in parallel to the transmitter output, and use two antenna tuners to get equal power into each antenna. The first approach is quite commonly used on VHF and UHF in multi-element commercial antennas, where each element is identical, but different antennas will likely have different impedances, and controlling the power ratio between them becomes a challenge.

For receive, you will need switches or relays to bypass the matching and power division.

Source record: 156599

I've spent an interesting morning in my workshop measuring balanced transmission lines. The 75 ohm number I came up with yesterday is clearly in error, probably to a balun problem. Here's today's results:

Method (1) TDR.
Using a Tek 1502B TDR (50 ohm reference), I measured the reflection coefficient of the following transmission lines and derived the indicated Zo:

(a) 300 ohm TV twinlead: p= 0.72, Zo = 307 ohms.
(b) RG58A: p = 0.00, Zo = 50 ohms
(c) Category 5e Ethernet twisted pair: p= 0.32, Zo = 97 ohms.
(d) The infamous black Zip Cord: p=0.34, Z0 = 101.5 ohms.

Method (2) - RF Bridge
Using a GR916A RF bridge, signal generator and an HP8558A spectrum analyzer as the bridge detector, measure Z for open circuit (Zoc), Z for short circuit (Zsc) and then Zo = Sqrt (Zoc*Zsc). Use a choke balun consisting of 10 turns of the cable under measurement through a T225-61 ferrite core.

(a) 300 ohm TV twin lead:
@ 3MHz: Zo = 278.5 ohms
@ 5 MHz: Zo = 296.2 ohms
@ 10 MHz: Zo = 307.9 ohms
(b) RG58A - not measured
(c) Category 5e Ethernet cable
@ 3 MHz: Zo = 100.7 ohms
@5 MHz: Zo = 96.7 ohms
@12 MHz: Zo = 101.3 ohms (could not measure at 10 MHz; Zsc was outside bridge range.)
(d) Zip cord
@3 MHz: Zo = 100.1 ohms
@5 MHz: Zo = 102.3 ohms
@10 MHz: Zo = 101.9 ohms

The close agreement of the 300 ohm and Cat 5e cable with the nominal values gives me confidence that the zip cord measurements are pretty close to what I measured today. I also see pretty good agreement between the TDR and GR bridge.

Cable Loss:
I constructed two resistive matching pads 50 ohms : 100 ohms and fed a 16.2 ft long section of zip cord with a signal at 4 MHz. The far end was terminated with a precision 50 ohm load, following the matching

pad. The signal generator was connected through the other matching pad. The line should, therefore, have been matched at both ends. I measured the input and output voltages on the transmission line using 10:1 probes connected to a Tektronix TDS430 scope. The scope was configured for peak-peak voltage reading off the two channels and these values were used to calculate the loss.

I measured 3.01 dB of loss for 16.2 feet. This translates into 18.5 dB/100 ft, pretty close to the 20 dB/100 ft I measured yesterday.

By the way, the spec on 5e Ethernet cable is Zo = 100 ohms +/- 15%. Checking the quoted loss figures indicates that 5e Ethernet twisted pair is a decent RF medium, with losses at 4 MHz of only 4.1 dB/100 meters, or 1.25 dB/100 ft. Its power carrying ability may be rather limited, as the conductor size is No. 24 AAWG ((0.525 mm), but the loss factor is quite decent. Since you have 4 pairs in the standard 5e cable, you could combine the pairs and increase the power handling.

Hi.

Just yesterday, I bought myself a TA-33Jr and a Ham-M rotator (all used, of course :-). I plan to mount these on a small 32' TV tower. I plan to add some guy wires to the tower.

After reading a few items about the Ham-M, I want to maybe modify it a bit, and am wondering if I am on the right track. Any help or advice about the following would be appreciated. This rotator has the old brown control box (bakelite?) with the single lever switch.

Should the following modifications work okay? Is there any pit-fall or possible problem of which I need to be made aware? Has anyone else done any mods like these?

My understanding of the control circuitry is as follows. The single lever switch for this controller has, I understand, five positions, with the middle position being the neutral "Off" position. The left and right "inner" positions energise the meter circuit, to allow the user to read the position without turning the rotator. The left and right "outer" positions continue to energise the meter circuit and, as well, energises the motor/brake circuit, with the motor windings phased (by the capacitor) for the required direction.

First, I would like to modify the control box to add an overall toggle "power" switch after the fuse in the power line. Then I would like to move the meter circuit transformer primary's switch connection from the lever switch to the power switch. This way, the meter circuit is always active when the control box is turned on by the new toggle switch; no need to press the lever switch to read the rotator position.

Secondly, I would like to add an "immediate calibrate" mod, by adding a N.C. push-button switch between the meter input resistor network and ground. Pushing this button would then effectively disconnect the rotator pot's wiper arm, so that the meter immediately goes to full scale deflection (without having to turn the rotator). This would allow one to adjust the meter scale calibration more easily, without moving the antenna.

Thirdly, I would like to re-wire the primary of the motor/brake transformer so that it will be energised from the lever switch's "inner" positions as well as the outer positions. This would

effectively add a simple brake delay by energising the brake solenoid with the lever in the "inner" positions. To actually turn the rotator, the lever switch would still have to actually go to the outer positions, to energise the motor windings in the rotator. The user would then move the lever switch "in a bit" to de-energise the motor and allow rotation to stop (or at least slow down enough) to then let go all the way and allow the brake wedge to lock the rotator. WOULD THIS ALLOW NOT HAVING TO ADD A "TORTION BAR" TO THE TOWER AS ROCOMMENDED IN THE HAM-M MANUAL?

Finally, I have read somewhere that the original meter circuit can be quite inaccurate due to mains voltage fluctuations on the primary of the meter circuit transformer. So, I would like to add some kind of voltage regulation on the secondary side of the meter circuit transformer. DOES ANYONE HAVE ANY RECOMMENDATION FOR THIS? IS THERE A "TRIED-AND-TRUE" MODIFICATION TO DO THIS?

Are there any other simple mods that I should add to the Ham-M rotator?

Oh, and one other question: is there any freeware and/or articles available on the net to add home-brewed computer control to the Ham-M? (I.e. to build my own control I/F circuit and run freeware to control it?)

And another question. I am new to using beam antennae. In high winds and stormy conditions, is it better to aim the boom of the antenna into the wind (so the elements bear the brunt of the wind), or is it better to aim the boom broadside to the wind (so the elements are aligned with the wind direction)? Does it really matter anyway (since the wind can unexpectedly shift)? Is there, perhaps, automated control mods or circuits available to automatically aim the antenna during high wind conditions (i.e. to move the antenna with the wind direction)?

It's not too bad. You'd lose 1 dB, or 21 watts, in the first five feet. The next dB, or another 16 watts, would be gone in the next five feet. The third five feet would take another 13 watts. And so forth. Copper is a good thermal conductor, so the heat would be distributed more evenly along the cable. I'd think that 100 feet should handle 100 watts, at least intermittently, if the cable was laid out to allow some air circulation. I've used lossy coax as a dummy load on a number of occasions.

If you are restricted in space, and must accept the multi-band vertical like I had to, add an extra $100 and get the Gap Titan DX. Needs no radials, is basically a vertical dipole (kind-of), is quiet for a vertical and I love it.

Check out all the reviews on http://www.eham.net/reviews/, this should help.

149. Common-Mode Currents VS Loads

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-04 20:06:25 UTC
From: CAM <Cecil.A.Moore@IEEE.org>
Message-ID: <3BBCC141.4090105@IEEE.org>
Source record: 156602

I promised to run an experiment to see what happens to
common-mode currents as the differential load is varied.
A #61 toroidal pickup loop was placed between the XMTR
and the tuner. The output was measured across a 110 ohm
resistor by a 100MHz O'scope. Frequency was 7.1 MHz.
Power input to the tuner was 50 watts. Balun was ten
turns of RG400 on an FT-240-61 toroid. Here are the
peak-to-peak results from the O'scope.

XMTR---tuner---coax---||---coax---balun--ungrounded
#61 toroid differential load
pickup loop

resistive load O'scope deviation
50 ohms 1.0 division
300 ohms 3.5 divisions
600 ohms 4.2 divisions
1200 ohms 6.0 divisions

It appears to me that the common-mode current and the
differential load are not "unrelated".

1. Was the tuner re-adjusted each time the resistive load was changed to present 50 ohms resistive to the transmitter?

2. "The output was measured across a 110 ohm resistor . . ." Was this subsequently replaced by 50 ohms, 300 ohms, etc? Or,

3. Was the "resistive load" placed acorss the toroid pickup loop? Or was that the 110 ohm ungrounded resistor?

Sorry to be dense this afternoon, but I don't seem to follow what you did.

Thanks, Cecil, and sure like the new call . . .

I have a used 4-BTV without the spider hub and the 6 alum 3/8dia x 13" rods.The vertical is ground mounted with 2 radials per each band as shown in the instructions.
It works ok for a vertical on 10 / 15 / 20 / band with a vry low swr. The 40 meter swr is 3 :1 at the lowest.Could this high swr on 40 meters be caused by not having the spider element or does it just sound like I might have a bad 20 meter trap. This spider element mounts right above the 20 meter trap.

Cecil:

Heh, heh... nice piece of experimental work, but... what is the common mode rejection ratio of the O'scope, the torroid pick up, etc... etc...

BTW... am I wrong or are you and Tom arguing at cross purposes on this issue?

I thought Tom stated that common mode *IMPEDANCES* --are not related-- to differential mode *IMPEDANCES*.

Which is essentially correct.

i.e. an impedance to impedance comparison where those impedances have no correlation. BTW... you had better first define what you mean by those impedances so that all are on the same page. Impedances just are physical manifestations of structures that just sit there and are what they are! Impedances ordinarily do not vary with the currents that flow through them!

While you are stating that common mode *CURRENTS* --are related-- to differential mode *IMPEDANCES*.

An entirely different relationship than what Tom stated.

Incidently IMHO, I believe that you are correct as well That is... when there are cross-coupling impedances between the modes.

I believe that you are both correct, and just don't know it!

Best,

154. CD 44 Rotor & Control

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-04 21:56:47 UTC
From: fmaxsc@hotmail.com
Message-ID: <3bbcdaa6.289060839@nntp.ix.netcom.com>
Source record: 156609

$70.00 plus half on shipping from Greenville, SC! (The control box is worth this)

A CD44 rotor and the CDE control box for sale.
The rotor rotates 30 degrees one way and then stops. It rotates back to the original position.

The face of the box (glass and front face) is excellent; the top of the control box has a scratched area the size of a quarter. This is the box with three levers.

The rotor has two plastic rings that hold bearings; those rings are not solid pieces (if they are supposed to be). Each plastic ring (upper and lower) has one break and seems to be missing a few bearings.

Here's a tip for measuring Z0 with a TDR. Terminate the cable with a physically very small trimpot. Adjust the trimpot for the smallest reflection from the end of the cable. Then measure the trimpot R with an ohmmeter. This works well even if the cable is lossy (which causes a rising TDR return voltage that can make the measurement otherwise difficult. It'll also prevent potentially misleading results caused by reflection of the common mode wave which you'll see occurring some time before the differential mode wave hits the end of the cable.

Clearly, measurement of Zo is fraught with sources of errors.

It strikes me that some parameters we can measure quite accurately, indeed our measurement error might be much smaller than manufacturing tolerances, whereas others may be very difficult to measure directly.

How is this for an approach to obtaining a ball park figure for Zo of these open wire lines:

1. Measure the average conductor diameter and spacing physically (using a caliper) (take several samples);

2. Measure the resonant frequency of a convenient measured length of line somewhere of the order of the freqency of interest, say about 5m (15') should resonate (L/4) somewhere near 10MHz (again average several measurements).

3. Calculate the velocity factor using the measured frequency and line length;

4. Calculate the effective relative permittivity using the velocity factor;

5. Calculate the Zo using the conductor dimensions and the effective relative permittivity.

The method is based on parameters that can be measured with very simple equipment.

Any thoughts?

Owen

Why? Even though mine has one, it's NEVER been on. And I have put
impressive amounts of RF through it into a wire antenna in back of my house.
You think it's there to cover up a problem? Because I don't see any with
my Palstar. Infact i'm starting to wonder why the thing even has one.
I guess i'll have to try and abuse it hard to heat it up. That way it will give
me a reason to turn the fan on..... Oh Well.

73 Tom.......I hear an echo ;o)

Jason, I never said the SWR had anything to do with how well the antenna is getting out. I just listed the SWRs I got when I tuned the antenna for the conditions at my QTH. Some of these multiband verticals don't tune up as well as the mfg. claims so I posted what I got for the person who asked about the antenna. There is not a huge difference in radiated RF between 1.3 and 1.9 SWR. Unlike you Jason, I don't spend all my time reading about antenna theory and posting the articles to a web page. I spend it building antennas, purchasing new antennas to try out and getting on the air with them to see how well they work. I provided useful information to the person who inquired about an antenna that I have actually used on the air, while all you saw fit to do was criticize my post. Enough said, Ken, N0VZ

160. Smart Antennas UMTS

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-04 23:28:55 UTC
From: riccardo <selvaggio7@libero.it>
Message-ID: <Xg6v7.25296$0Y2.2888818@news.infostrada.it>
Source record: 156613

Hi,

I've started to study about smart antennas and their
Positive effects on coverage and traffic load for UMTS.
There is someone that can indicate to me some interesting
basic or more deep documents I can find on internet
(or why not send to me something) about these issues ?

Thanks,
Riccardo

161. Re: Info on 4-BTV vertical

Newsgroup: rec.radio.amateur.antenna

Source record: 156614

The "spider" provides a form of capacitive loading at a specific point on the antenna, similar to top loading on a vertical. Absence of the spider could indeed affect your 40-meter SWR. I last used a 4-BTV in 1970, but as I recall it tuned up reasonably well over the 4 bands that it was designed to cover.

Just a note that your very low SWR on 10 through 20 might be telling you that some more radials would be helpful. They would decrease your ground loss which is probably the major component of your driving-point impedance.

You may not know that you can add the Hustler 80-meter resonator and stinger at the top of the 4-BTV to provide 80-meter coverage. Narrow bandwidth, but it works.

I had a Gap Titan DX for a couple of years, it worked just fine, no radials
tuned up fine on all bands, took about 3 hrs to assemble.

How to measure Zo... (?)

I was thinking that you could just put a 9-volt battery across a decent length of cable with an inline milliamp meter, switch it on, and then measure the current REALLY REALLY QUICKLY. :-)

More seriously, several years ago, one of the scope manufacturers (Tek?) was giving away very fast pulse generators (cheap little circuit cards). I've got one hidden away somewhere. I wonder if (given a decent length of cable) launching a fast, short, neat-and-tidy pulse down the line and measuring the E/I ratio *on the way in* using a decent 2-ch scope and a low value series carbon resistor (to convert the I to an E).

The rep rate would be set to allow the reflection to die off before the next pulse and the continuous nature of the pulses (with appropriate triggering) would allow one to play with it all day.

The circuit would have to be connected using RF "common sense" (not 2-foot clip leads) and by varying the frequency a bit, one could ensure that the results were consistent.

I would think that this would be the ideal way to measure Zo and should give reasonably accurate results (better than 20%, perhaps +/- 10%).

>multiband performance of the antenna.

Hi Steve,

My work concluded some time ago that the geometry means very little,
it is in the number of kinks in the wire. At my page in the "under
Construction" portion (end of the page):
http://members.home.net/kb7qhc/antenna/fractal/Constant%20Wire%20Comparisons.htm
I have derived an ordering factor that boils out the complexity to
find the advantages to be found (if any) are correlatable to the
number of edges (or wires in EZNEC terminology) in the structure.
However, this is a first pass attempt (can I emphasize rough cut?) to
answer some queries here in how to cut any design to length for a
given frequency.

For us, this is a standard expectation. I stopped asking this
question after 5 years and decided if I was going to find out, I would
have to do it myself; because it became increasingly obvious that the
experts didn't have a clue and seemed to derive their income from not
knowing.

165. NY/NJ/PA "Radio" Octoberfest this Saturday

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-05 01:51:24 UTC
From: k3bu@aol.com
Message-ID: <20011004215124.08376.00001069@mb-ch.aol.com>
Source record: 156618

Reminder.
NY/NJ/PA "Radio" Octoberfest this Saturday

You are all invited to (Radio) Octoberfest at Verkhovyna Mountainview Resort in Glen Spey, NY (NY,NJ,PA tri-state area) hosted by the Tesla Radioclub and Ukrainian-American Cultural Foundation - UACF on October 6, 2001, starting at noon till ???

Come and have fun meeting other hams, DXers, contesters, while having good time and drinking Octoberfest beer. Enjoy Ukrainian and German food, listen or dance to endless polka's. Wear your badge, hat or shirt with callsign proud and meet other radio aficionados around the "radio" table.

140 acre Verkhovyna resort is the new home to Tesla Radioclub N2EE station. Join the semi-serious discussion of how many towers do we need to put up there. Come, join the club and get a free beer.

Directions:
Take Hwy. 84 to Port Jervis, NY exit 1; follow Rt. 6 through Port Jervis to traffic light with Rt. 97/42 signs, go through and follow Rt. 97 west for 10.8 miles to Pond Eddy (motel on right, bridge on left), turn right onto High Rd. (Rt. 41), go up the steep hill for 1.7 miles, Verkhovyna is on the left. Plenty of parking.
Maps and sattellite view of the resort are at www.UACF.net home page under directions.

See you all there and join us yodeling in Morse code :-)
Nazdorovya, Ein Prosit!

Yuri, K3BU
pres. Tesla Radioclub

Hi George,

In an unbalanced system, Cecil varied the load to show that the
changes in the CM current (with change in load) are consistent with a
DC analysis of the bridge this circuit describes. It is a causal,
linear correlation between the DM current and the CM current.

Dennis, thanks for your follow-up, but ...
never mind.

I investigated the control box this evening, and I now see why
none of what I wanted to do will work:

1. the motor winding circuit is connected by the lever switch
before the motor/brake transformer primary (and this is
probably a good thing, to reduce arcing at the switch for
motor windings, but it will not allow me to implement a
"manual brake delay" using the lever switch, as written in
my original newsgroup post) :-(

2. the trim-pot cannot be disconnected from ground (for the
"instant" meter calibration mod), since it is riveted
onto the chassis :-(

Oh, well, if anyone has any thoughts or ideas on how to
implement "instant" meter calibration or a "manual" brake delay,
please let me know. Also I would still like to know how to
implement a regulator for the meter circuit.

Hi OM,

The success will be with the switch. Other problems will arise with
parasitic couplings(far cheaper to fix).

This is ancient technology, but the long standing champion of fast
switches (25-50 years ago from Tek) was mercury wetted (yes a physical
switch). I don't think I would be far off to spec it in the sub
nano-second risetimes. Another candidate would be in their sampling
head used to extend the bandwidth of scopes to 1 GHz back in the
50's-60's.

Drink,

Check out - YAESUVX5-subscribe@yahoogroups.com

Great info and an email list server.

My favorite 2 bander is a Comet SMA503. When I really need the gain on 2m
or 440, I use a Pryme RD-98. I have gone thru 5 or 6 ants for the VX5R and
have settled on these two and the stoock ant. Note that the VX5R will
respond to more rec gain with added intermod.

RE: Ham M Rotor

Reply
by WA8RUO on November 17, 2000
Mail this to
a friend!
Patrick,
The info that K0RS gave you is right on the money.
I remember "back
then" that there were some "brake delay modules"
being sold that
would lessen the wear and tear on the rotor. I
opted for the "poor man's
version"... a manual miniture toggle switch. As I
recall, de-energizing
the brake also turned on the panel light... a neat
little reminder that the
brake was de-energized.
If you are interested in thid mod, let me know.
73, Charlie

I notice you're using a TA33Jr so really that brake elimination may work
out just fine. As for regulating the readout, thats a tough one. My
Ham-m meter wandered a bit but I really didn't find it
objectionable...nothing more than about 1/8" IIRC. If yours is moving
much more than that, there may be a different problem.

IIRC, the freebee little circuit card pulse generator was in the nano-second rise time range. So long as the pulse gets up and down (with a stable "flat" top) before the reflection from the leading edge arrives back to foul the display, then it should be (dare I say ?) a trivial measurement. Isn't it ~about~ a nanosecond per foot ? Therefore, a "decent length" of cable-under-test would be perhaps 50 feet (a relaxing 100nS window of opportunity).

I'm not claiming that this measurement would be immune to mistakes; but the numbers do seem to be within range of any reasonably well equipped electronics workbench.

Of course, a jaded eye would still be required to ensure that all the silly errors are noticed and removed. Obviously the experiment could be tested with (more-or-less) known samples of 50 and 75 ohm coaxial cable to see if was making sense at those two data points. I guess even dummy loads would provide additional data points (without checking the additional complexity of other possible errors from the cable reflections).

This would be a *direct* measurement of the "surge impedance" which is after all exactly what we are discussing here.

de VE1BLL@rac.ca /VE3

PS: All this thinking about pulses and scopes is reminding me of my involvement in a project (around 1986?) to modify a MW navigation system (Argo - NOT the satellite) to be resistant to evening and night-time skywave. We were sending signals from Halifax (Dartmouth actually) out to Sable Island (200-odd miles away) where the equipment out there would "count to ten" (so to speak) and send back a phase-locked RF pulse.

There were cesium references (atomic clocks) at both ends. Everything was referenced from the cesiums for the purposes of the simple proof of concept testing. The real system would normally self-lock from a master station.

I designed and built a "Sync Pulse Delay Unit" (74LS logic) which had thumb wheel switches to provide an exact, repeatable delay in microseconds up to 9.999999 seconds (it was also cesium clocked). The repeatability was sufficient that you could dial in the appropriate delay and witness the leading edge of the first RF cycle (at the 455 kHz IF) rising hitting the selected trigger point exactly time after time.

The phase could be picked off in the first few cycles (the ground wave) before the skywave arrived (later) and screwed up the signal.

The basic principle was that the skywave took the long road home and by the time that it arrived, we already had the phase. The phase (and "lane

counting") from at least two fixed reference stations is how the Argo navigation system worked. The Argo MW navigation system was used for positioning oil rigs back onto the wells in the middle of the ocean before GPS was up to the task.

The proof of concept worked perfectly, but by then GPS was obviously starting to take over. As far as I know, the project never went any further.

Sorry - I've drifted off topic...

The output of the pick-up loop was measured across a 110 ohm resistor.

> 3. Was the "resistive load" placed acorss the toroid pickup loop? Or was
> that the 110 ohm ungrounded resistor?

That was the 110 ohm resistor across the pick-up loop.

I believe that Tom said that common-mode currents are
unrelated to differential impedances. I can't seem to find
that posting, however.

To the earth through the eather? I later ran the experiment using
an antenna system that is resonant with 88ft of feedline. A tuner
was used to obtain a 50 ohm load for the transmitter.

feedline length O'scope divisions approximate load
88ft 0.8 50 ohms
92ft 1.3 51+j90
100ft 2.2 77+j315

Hi Ryan.

First, have a look at
http://hem.passagen.se/sm0vpo/
for some nice antenna tips on a very cheap and simple multi-
band balcony antenna for limited space.

I guess Your present antenna is "hanging" from Your balcony?
Anything radiates, the question is how much. And, do You have
any counterpoids, or grounding system? In the very worst case,
Your only ground is Your rig chassis and the tuner, capacitively
coupled to the mains and plumbing inside the building. This is
not very good... Try to get some RF ground. Anyting is better
than nothing (e.g. the railing og the balcony, if metal).

I would say, that a vertical antenna would work sligtly better
than Your random wire (higher efficiency). The "rollup" is
forming a coil at the feding point of Your antenna, lowering
the resonant frequency. If the antenna (incl. rollup) equivalent
length is shorter or equal lamdda/4, you will have an current
distribution that could be better.. Max current will be in the
coil, had it been in the antenna it would have radiated
"better".

But, if I were You I'd go for the "ancient" end-fed Zepp.
Simply Use Your "hanging" wire as usual (cut of the coil
lenngth), but feed it with a balanced (e.g. 300 ohm TV)
wire. In the tuner, connect both leads to the balanced output,
in the antenna end connect just one of them, the other one
being unconnected (in this case, using the railing as RF
ground is perhaps not a very good solution... better have
it unconnected).

It will perhaps not be a very good antenna at lower frequencies.
Approx 35 feet would be suitable for 14 MHz and higher, but
it will radiate also if shorter, and also on lower frequencies.
Main rule: longer or equal than lambda/2 makes a good antenna.

Good Luck,
"Charlie", sm6hcj

Dont be fooled by the 5/8 waveleght mystique. In one of the ARRL antenna compandium books, was a very article about 5/8 vertical, I think it was volume 2. , but not shure. In L.B.Cebik's website is also a good article on subject: www.cebik.com/58.html

The point is, that when you model 5/8 vertical over perfect ground. It shows 3 dB gain over 1/4 vertical, but in real world you cant realise that gain. If you want a 40/17 combo, of course 5/8 is a practical solution, but in many times it's not worth of extra cost and size.

Odd that they installed one then.

I know the ATR30 will handle over 5KW carrier for extended periods
without getting warm, so I can't imagine why anyone would need a fan
on a tuner.

Unlike MFJ...Ameritron has always rated tuners in RF output power
under worse case conditions, or clearly defined conditions.

I don't know which advantage do you expect form such configuration, anyway
you could use a Wilkinson divider. It will split the tx power into the two
antennas, so the total power will be the same, but the beam will be
different.
To switch antennas for receiving you can apply a relay on each side of the
resistor to shortcut to ground or to open the ant you do not want.
WARNING: DON NOT FORGET THE RELAY ACTIVATED WHEN TRANSMITTING; HALF OF THE
POWER WILL HEAT THE RESISTOR!

If you look at reviews of the Gap verticals (even QST reviews), they
aren't so good on low bands. All "no radial" or small radial verticals
are that way.

From Champion Radios "HF Vertcal Performance Test Methods and
Review", they show a Gap Titan as 19.2 dB down from a conventional
marconi vertical in actual FS results on 80 meters!!! 19.2 dB is a big
loss.

On 40, the Gap Titan is only 3 dB down, but still worse than things
like Butternut.

With a good ground system, the Butternut or any of the other trap
verticals are the best bet. Without a good ground system, nothing will
work well on lower bands. You might as well use a low dipole.

The description of you test setup is so vauge, no one can have any
idea what you are measuring. I suspect you don't know what you are
measuring either Cecil, if the description is anything like the setup.

For one thing, if you had a small floating resistor load like you
describe, you could have virtually NO common mode current.

I'm most interested in how you verified you are measuring what you
think you are measuring, especially since using a scope would be a
very very sloppy method of measuements of voltage across a current
transformer unless you took extraordinary measures of ensuring no
common mode response on the unbalanced scope input.

You would be far better off, and the results far more reliable, if you
use a physically small self-contained meter to read common mode than a
poor system that makes a transition fromn a balanced toroid (you hope)
to an unbalaced scope through long leads.

99% of reliability in a measurement is rooted in how the test setup is
configured.

Rick, K1BQT wrote:
"Would you like to borrow my common-mode meter?"

Terman says: "An antenna carrying current will induce a voltage in another antenna in the vicinity; i.e., the two nearby antennas act as though they were coupled. One can accordingly postulate an actual impedance Z12 between the antennas that has the same significance as jomegaM in the ordinary coupled circcuits of Sect. 3-3 to 3-5." Sections 3-3 to 3-5 cover inductively coupled circuits.

Common-mode on a transmission line that baluns try to prevent is that produced by the differential-mode in the transmission line. Mutual impedance is the result of coupling between modes. No coupling, no relationship between modes, but if one mode is the source of energy in the other mode, the coupling has the form of a mutual impedance. The current in one mode produces a proportional voltage in the other mode.

Common-mode current can not be unrelated to differential-mode impedances when the circuits carrying common-modes and differential-modes are coupled.

Best regards, Richard Harrison, KB5WZI

Tom:

When you live in Cal. with a postage stamp sized lot, with no room for any radials, and with all the CC&Rs and idiots that get mad even if you only put up that preverbal "wet noodle" because it "destroys" their view of the next yard, sometimes you have to REALLY compromise. I am lucky that my postage stamp is on a canyon and my neighbors are not complaining Yet. Not the tops, and I know if I work 80m it will probably be the guy down the block, but so far the Titan is the trade-off I needed, and I am pleased with its performance on 10m through 20m.

I have visited your website. You got kind of a nice little spread with a couple of cute little antennas Wanna trade?

Dennis

Contrary to some of the other comments, I don't have a lot of trouble understanding this setup. I would, however, lose the balun and try again. If there is a relationship between the load Z and the common-mode current, anything that attempts to surpress the CM interferes with determining the relationship, especially if it is non-linear.

In other words, why try to eliminate the very thing you want to measure.

And another thing, absent a differential input on the scope can you at least trigger the sweep from the transmitter and verify (if you didn't already) that what you are measuring is indeed rf at the same frequency.

I should clarify my badly constructed last sentence. My concern with
non-linearity is in the balun, not the relationship between Z and I.

Source record: 156553

I've spent a second interesting morning in the workshop pursuing the elusive Zo of zip cord.

Using the suggestions made in this thread, I've performed 4 measurements with different techniques. Here are the results:

(1) As per Roy Lewellen's suggestion, I installed a small 200 ohm trimpot at the end of a 17.3 ft length of zip cord. The opposite end was connected to a Tektronix 1502B TDR. I adjusted the trimpot to minimize the reflection. I then measured the trimpot with an HP3468A digital multimeter. Zo by this method is 114.9 ohms.

(2) Following the technique proposed by Owen Duffy:
(a) Measured conductor diameter = 0.048 inches
(b) Measured conductor spacing = 0.108 inches
(c) Computed Zo for an air-line with these dimensions (using the 120 arccosh(D/d) formula supplied by Roy Lewellen) as 174.1 ohms. (Using the approximation 276log(2D/d) yields 180.3 ohms)
(d) Measured Vf using the following technique. For two different lengths of zip cord, using a homemade test fixture and an HP8754A network analyzer, I measured 1/4, 1/2 and 3/4 wave transmission minima. The result of these six measurements is Vf = 0.662 +/- 0.015.
(e) Based on the mean Vf, calculate effective relative permittivity Er as 2.35.
(f) The Zo is then Zo air / Sqrt(Er). I calculate Zo = 113.6 ohms.

(3) As suggested by VE1BLL, I drove the terminated zip cord line with an HP8012B pulse generator and observed the E and I at the driven end. I used a Tektronix TDS430 scope for the E and I measurements, I being measured with a Tek TCP202 Hall effect current probe, with a 50 MHz rating. Zo is then simply E/I. The driving voltage was 6.04 v peak and the peak current was 58 ma, yielding Zo = 104.1 ohms. (The TCP202 does introduce some series L, of course.) The terminating R that minimized the reflected pulse was 108.3 ohms, which is yet another measurement of Zo.

(4) The Zo of a transmission line is approximately Sqrt(L/C). Using a GR 1650A RLC bridge, for a 17.3 ft length of zip cord, I measured C = 346 pF, or 20.0 pF/ft. (An 8.63 ft section yielded 19.9 pF/ft.) I then shorted the far end of the 17.3 ft line and measured the L, using a Leader LCR-740 RLC bridge, as 3.42 uH. Zo is then calculated as 99.4 ohms.

So, I have some measurements clustering around 114 ohms, and another group clustering around 100 ohms (including the GR916 bridge technique posted yesterday.) Anyone have a view on why I'm seeing such a

discrepancy?

I have a LOT of problem with this set-up. The words say one thing about
the locus of the pickup, and the diagram says another. Just where was
it?
If the purpose of the experiment is related to common mode current, and
the purpose of a choke balun (as described) is to reduce(choke) common
mode currents, why is the Balun there at all?
The original comment this is all about was about impedances, not
currents, so- why the claims about currents being effected? We all know
that cutting off the transmitter will stop both differential and common
mode current, but this does not mean stopping one of the currents caused
the other to stop, also.

202. Vertical vs. Inv L

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-05 16:50:30 UTC
From: Harry Williams <harry.w.williams@syntegra.com>
Message-ID: <3BBDE4D6.86B9B8F2@syntegra.com>
Source record: 156555

I am starting work on a low band antenna system and am debating about
two different ways to go.
First off the system will have sixty 130ft radials. One plan is to put
up a vertical
which is 5/8 wave on 40 (around 78ft) and then use that on 80 and 160 by
switching in appropriate
l/c circuit for matching on each band (linear loading on 160). The other
thing I am thinking about is to put up 65 ft vertical
mast and then connect a 128 ft top wire to that to form an inverted L
which would be 3/4 wave length
on 80 and 3/8 wave on 160. I would also switch between matching networks
with this configuration.

Any opinions out there on either one of these systems? The 3 band
vertical idea is from the "low band
dxing" book and the inverted L from an old QST article.

Thanks,
Harry - W0PIY

Steve,

You articulate this well and I can't dispute this. The original
leap from "if you bend up the wires you can fit the antenna in a
smaller space", which is the datum, to "fractals are optimum for this",
is a huge one without any apparent justification.

>To mitigate this issue when challenged, the fractal proponents will
>generally declare that all random, bent wire geometries are simply random
>fractals because they are self-affine, therefore, "see how well the random
>fractal works". If we were to agree that random geometries are simply
>random fractals, then we would also have to conclude that fractal antenna
>designs have been characterized and well understood for over 60 years and
>that assigning the term "fractal" to them changes nothing about the physics
>or our understanding of antenna performance.

I'd really hope Puente wasn't one of these proponents. I sort of bought
this argument at one point, but if you look at papers on frequency-independent
fractal arrays, some of which Puente has coauthored, you'll find that here
they draw a clear distinction between fractal and random geometries, since
random geometries were used first but fractals were found to improve on
them. To draw this distinction where fractals might have an advantage,
but then pretend the distinction doesn't exist when fractals are apparently
a disadvantage, would not be honest.

>While the self-similar fractal has an inherent disadvantage in terms of
>lowering resonant frequency, it has a significant advantage regarding the
>antenna's multiband performance at high frequencies. While I need to do a
>bit more work, it is my opinion that the high (or tight) wire compression,

>multiband performance of the antenna. Comparing the performance of the
>self-similar geometry with other highly compressed geometries that are not
>self-similar, I have found that they exhibit almost identical multi-band
>performance at high frequencies.

This would be more surprising, since basic consideration of frequency scaling of antennas would lead one to guess that good multiband antennas would be self-similar in geometry. On the other hand, now that you've pointed out your opinion, it is the case that no realizable fractal antenna element can be truly self-similar at several scales (since it must be both finite in size and limited in the number of iterations of the motif), so this is only an approximation and it may be that you can find non-fractal approximations which are as good. I'd still be surprised if you found one which is significantly better, however.

Dennis Ferguson

|I have a LOT of problem with this set-up. The words say one thing about
|the locus of the pickup, and the diagram says another. Just where was
|it?

Fair observation. I assume the diagram is correct, as it took a lot more effort to 'draw' it than to describe it. If the tuner is ungrounded, then it doesn't matter much anyway.

|If the purpose of the experiment is related to common mode current, and
|the purpose of a choke balun (as described) is to reduce(choke) common

I don't know what the "original" comment was. I'm commenting about the "original" post in this thread. Period.

Cecil's use of a (possibly) grounded oscilloscope for a detector may not be the best choice, but conceptually his setup is quite similar to Roy's current probe as described in "Baluns: What They Do and How They Do It", Figure 13.

AMATEUR RADIO NEWSLINE(tm) REPORT #1260 - OCT. 5, 2001

Amateur Radio Newsline report number 1260 with a release date of Friday, October 5th, 2001 to follow in 5-4-3-2-1.

The following is a Q-S-T.

A big week for ham radio in space as A-O 40 proves G-P-S works in space and P C Sat goes into orbit. These stories are first on Amateur Radio Newsline report number 1260 coming your way right now.

(Billboard Cart Here)

**

HAM RADIO IN SPACE: GPS EXPERIMENT COULD REVOLUTIONIZE SPACE TRAVEL

AMSAT reports another success with its AO 40 satellite that holds the promise of changing the way men travel into space. This, with word that that the on board Global Positioning System -- or G-P-S experiment has now undergone successful testing. Roy Neal, K6DUE, has the details:

--

ABOUT 20 YEARS AGO THE AIR FORCE PUT A RING OF SATELLITES IN ORBIT CALLED THE GLOBAL POSITIONING SYSTEM, “G-P-S”. THEY WERE DESIGNED TO SHOW WHERE IN THE WORLD YOU ARE, WITH PINPOINT ACCURACY. THE AIR FORCE USED THEM TO GUIDE MISSILES AND MILITARY AIRCRAFT.

THE SYSTEM WAS MADE AVAILABLE FOR PUBLIC USE A FEW YEARS LATER AND HAS BECAME A MAINSTAY FOR NAVIGATING AIRLINERS, SHIPS AT SEA, TRUCKS AND CARS ON THE HIGHWAYS AND EVEN HIKERS . NASA WANTED TO KNOW IF GPS ALSO COULD BE USED TO PROVIDE POSITIONAL DATA OUTSIDE ITS RING OF SATELLITES. THE SPACE AGENCY TURNED TO AMATEUR RADIO’S AMSAT CORPORATION TO HELP WITH AN EXPERIMENT.

NASA PROVIDED TWO G-P-S RECEIVERS WHICH WERE INSTALLED ON THE A0-40 SATELLITE. THE “A” RECEIVER TO TUNE IN AT APOGEE, THE HIGHEST POINT IN ORBIT., THE “B” RECEIVER WOULD LISTEN AT PERIGEE, THE LOW POINT.

JIM WHITE, WD0E, THE AMSAT COORDINATOR AND CHIEF OPERATOR, HAS JUST MADE HIS FIRST REPORT ON THE ACTIVITY. HE SAID ”WE RECEIVED A SIGNAL FROM ABOUT 52 THOUSAND KILOMETERS OUT WITH GOOD SIGNAL LEVELS. FURTHER DATE IS BEING GATHERED AND THOSE DOWNLOADED SO FAR ARE BEING ANALYZED.”

THEY WERE DOWNLINKED THROUGH THE A0-40 S-BAND TRANSMITTER. AMSAT VICE PRESIDENT FRANK BAUER, KA3HDO, WHO WAS INSTRUMENTAL IN SETTING UP THE EXPERIMENT, SAID IT WILL REVOLUTIONIZE THE WAY GPS IS USED IN SPACE. BAUER SAID MANY FUTURE HIGH EARTH ORBITING SATELLITES WILL BE ABLE TO TAKE

ADVANTAGE OF GPS FOR AUTONOMOUS NAVIGATION AND STATIONKEEPING

FOR THE AMATEUR RADIO NEWSLINE…ROY NEAL, K6DUE.

--

The bottom line. It now looks as if a ham radio satellite may help change the way men and machines travel to and from space. (AMSAT, K6DUE)

**

HAM RADIO IN SPACE: KODIAK STAR ORBITS PCSAT

The long awaited Kodiak Star launch, carrying the P C SAT ham radio satellite into orbit is a success. According to the AMSAT News Service, the launch took place from Kodiak Alaska at 02:40 UTC on Sunday morning September 30th.

Initial Information indicates that all satellites were successfully deployed, and that the amateur radio satellites have been heard by hams in many countries. One of the first reports came from Derek Studholme ZL1AKJ of AMSAT-New Zealand. Derek said that stations down-under heard good telemetry signals from P C Sat's first two passes over New Zealand

The launch of the Kodiak Star had been delayed several times due to weather conditions and Solar Flares. On board the launch vehicle were the P C Sat, Sapphire and Starshine satellites. P C Sat is a Naval Academy Amateur Radio satellite. The Sapphire satellite also has Naval Academy involvement in a joint venture with Washington University. Starshine was the primary NASA payload. (AMSAT Remailer, VHF Reflector, ZL1AKJ)

**

ATTACK ON AMERICA: TWO MORE HAMS MISSING AT WTC

Amateur radio operations have now wound down but there is more sad news from what's become known as 'Ground Zero' in New York City. It now appears that two more hams may have lost their lives in the terrorist attack on the World Trade Center.

The ARRL Letter says that Rod Coppola, KA2KET, was the transmitter engineer on duty for Public Broadcasting station WNET, channel 13 at the time the attack occurred. Coppola is 46 and lives in New York City.

Also missing is Winston Grant, KA2DRF. Grant is a computer technician with Empire Blue Cross - Blue Shield. He is 59 and lives in West Hempstead, New York. Neither man has been seen since the twin towers collapsed after being hit by hijacked jetliners on September 11th. (ARRL)

**

ATTACK ON AMERICA: FINANCIAL ASSISTANCE FOR MISSING ENGINEERS FAMILIES

In a related development, the Portland Chapter of the Society of Broadcast Engineers and the ARRL both report that a fund has been established to assist the families of broadcast engineers still missing at the collapsed World Trade

Center. Checks can be sent to the Ennes Educational Foundation Trust % The Society of Broadcast Engineers Inc, 9247 N Meridian St., Suite 305, Indianapolis, Indiana. The Zipcode is 46260. Please mark your envelope to the attention of the “Broadcast Engineer Relief Fund.” (ARRL, Portland SBE)

**

AMERICA UNDER ATTACK: INDIANA HAMS SET UP COMMS AT GROUND ZERO

Ham radio operators from Indiana were among those who made the trek to New York City to aid in rescue efforts after the September 11th terrorist attack. Their job was communications. Amateur News Weekly’s Jack Parker, W8ISH, has more:

--

Thirty-six hours after the first airplane crashed into the World Trade Center Indiana's Task Force One was standing at the ground zero. Among the 62 members of this elite Search and Rescue team were two Indianapolis amateur radio operators.

Veteran firefighter Jim Curseaden, KB9ZFF and Ed Elrod, W9PTO made the 14 hour road trip to help with disaster efforts. Both men make up the communications arm of this search and rescue team.

The moment they arrived each man began setting up a UHF communications link from the ground zero to their staging point several miles away at the Javis convention center. According to Jim Curseaden, getting UHF signals through the concrete canyon of New York City was a major challenge.

Ed Elrod said they first installed a repeater on a nearby building and directed a
Yagi antenna at the mountain of rubble. The Javis convention center posed another radio obstacle. Hand held radios could not reach the repeater.

To fix this problem, Elrod wired a up a remote base on the roof of the convention
center. This new link made it possible to communicate with the Indiana search and rescue personnel above and below the world trade center ruins. Ed Elrods most inspirational moment came during his second trip out of the devastation.

All week hundreds of people had been lining the streets, cheering and showing signs of support. When heavy rains began dousing New York the crowds disappeared...He said the contrast was amazing. The streets were nearly empty; except for one lonely figure standing in the rain. It was an elderly woman, holding a sign that read: “Thank You.”

Reporting from Indianapolis, this is Jack Parker, W8ISH

--

The hams from Indianapolis were not the only ones who traveled to New York City to help in relief efforts. We plan to profile others in future Amateur Radio Newsline reports. (ARN, W8ISH)

**

ATTACK ON AMERICA: DOD WILL NOT GIVE UP ESSENTIAL SPECTRUM

In the wake of the September 11th terrorist attacks on New York City and the Pentagon, the Defense Department has renewed support for its view that it shouldn't give up its spectrum to make room for consumer wireless products. Congressional auditors say that the proposed changes now could pose a further threat to national security. Amateur Radio Newsline's Norm Seeley, KI7UP, has more

--

Supporters of the mobile communications industry still say that transfer of some current military spectrum to the private sector is essential to fill the high demand for such services as the next generation of mobile phones and wireless Internet access. But Congresses' General Accounting Office says that if the Defense Department makes room for new wireless consumer products before more research is conducted, it could endanger the nation because of potential interference with Pentagon operations.

And it goes even further. Defense Department officials say that besides creating interference, moving all defense systems out of the current spectrum would take until 2017. That, says the DoD, would cost billions of dollars to orbit new satellites and otherwise accommodate military needs.

In the meantime, the Federal Communications Commission announced on September 24th that it will expand the possible uses of the 2500 to 2690 MHz band. That spectrum is currently used for fixed wireless services. New rues may eventually include a mobile component so that the spectrum can be used for 3 G services such as high-speed Internet access or music and video downloads.

The FCC says that it had considered reallocating the 2500 to 2690 band as a primary allocation to new 3 G wireless service. Because of the outcry against taking the spectrum from schools and other incumbent users it instead voted to create a possible shared allocation instead.

The FCC says that the flexible allocation would allow some portable data applications to be offered under existing service rules and could provide flexibility for offering other new advanced fixed and mobile services in the future. But it added that it would have to explore service rules that would apply to allow mobile operations in the band in a separate future rule-making proceeding.

For the Amateur Radio Newsline, I'm Norm Seeley, KI7UP.

--

A September 2002 deadline by Congress for an auction of new spectrum licenses for wireless services might be delayed because of the Pentagon's resistance to any allocation change. (Published news reports, FCC actions)

AMERICA UNDER ATTACK: HAM RADIO TRACKS THE RUN FOR AMERICA

They did it to show support to the firefighters, law enforcement agents and all Americans involved in the effort to rescue the victims of the recent act of terrorism. This, as Navy Ensigns Daniel Campos and Christine Fix, coordinated a relay run to carry our national flag from Virginia to New York City.

The goal was to carry the Stars and Stripes from the Pentagon to the World Trade Center. The run began on Friday September 28th and continued overnight until they arrived about 1800 UTC Saturday. Their route was tracked using the Global Positioning System capability of the United States Naval Academy’s Ham Radio club. Computer generated maps were able to show live the progress of the runners along the way. (VHF Reflector)

**

ATTACK ON AMERICA: MOROCCO CQWW CONTEST STATION CANCELS

The September 11th terrorist attack is now having an effect in the world of ham radio contesting. This, as Al Crespo, NH7A, tells the Ohio Penn DX news that his CN2AC CQ World Wide SSB Contest operation from Morocco has been canceled. Al says that he will instead operate from Maui using his NH7A callsign. (OPDX)

HAM RADIO HELPING HAND: IHS NEEDS OPERATORS FOR HONDURAS

International Health Services says that it needs ham radio operators to accompany medical and dental teams to villages in Honduras. According to an Internet posting by John Kirckof, KB0UUP, most of these villages I-H-S visits have no electricity or phones. Kickof says that IHS is often are the only medical care these local people will ever see:

--
In-Q: Honduras is the...
Out-Q:...each mission in February.

--

Kirckof, who is the Communications Director for I-H-S says the group will provide High Frequency gear for any operator who does not have his or her own portable rig. Both men an women are welcome to apply. Sign-up is now until about mid October. For some basic information, visit www.ihsofmn.org or contact John by e-mail to jmkkek@runestone.net. (KB0UUP, ARNewsline(tm))

**

SURVEY: CELL PHONE CURBS FAVORED WHILE DRIVING

Three out of four adults in the United States favor laws to curb the use of cellular telephones while driving. This, according to a survey released by a highway safety group. And its a survey that has some ham radio operators concerned as well. Amateur Radio Newsline's Don Wilbanks, KC5MFA filed this report:

--

The poll of 1,001 adults was carried out July 1st to the 19th by the Louis Harris organization for Advocates for Highway and Auto Safety. This is a coalition of consumer, health, safety and insurance groups who say that they are working to make U.S. roads safer. The results are almost startling.

Though nearly two out of three people surveyed report owning a cellular phone, the poll found a lopsided 76 percent backed restricting their use by drivers in motion except in emergencies. In fact, the poll found that mobile cellular phone use in vehicles topped the list of concerns that people wanted addressed. Cell phone use was closely followed by drunk driving and improving safety at intersections.

This poll and others like it are of concern to radio amateurs and operators of other mobile two-way radio gear. Currently, no federal law bars the use of cell phones while driving but several states
prohibit phones being held by hand while driving except in emergencies. Two-way radio users fear that any across the board federal ban on using a cellular phone while driving might also be
applied to other radio services as well.

Meantime, another report from the National Conference of State Legislatures says that laws suggesting bans on drivers using hand-held cell phones have now been proposed in 40 states. As previously reported, a measure in New York is recently won approval and at least a dozen municipalities have also established mobile cellular telephone bans.

For the Amateur Radio Newsline. I'm Don Wilbanks, KC5MFA, reporting from New Orleans.

--

The survey also says that all of these enacted and proposed laws appear to have widespread public support. (From media releases and published news reports)

**

SERVICES TO HAM RADIO: LOGBOOK TO THE WORLD UPDATE

Project Manager Wayne Mills, N7NG, says that access to the ARRL's proposed Logbook to the World will be for everyone. Bill Pasternak, WA6ITF, reports:

--

In a note to Pete Smith, N4ZR, and posted to the VHF reflector, Wayne Mills says that the only charge will be for usage. Mills explains that there will be a charge when utilizing a QSO record for a specific award such as the DXCC, Islands On The Air, Worked All Zones and the like.

Mills says this means that users will only pay for what he calls usable "QSL's. You will not have to pay for attempts to get a QSL as you currently do when you send them via mail -- whether direct or via a bureau. Mills believes should result in a dramatic saving as compared to tradition methods of obtaining QSLs.

Mills also notes that five years is about as far back as Logbook of the World will probably ever go. Initially says Mills, it won't go back even that far. This he says will be an attempt to manage the initial data in-rush.

For the Amateur Radio Newsline, I'm Bill Pasternak, WA6ITF.

--

In addition to his work on Logbook to the World, Wayne Mills, N7NG, is the Membership Services Manager for the American Radio Relay League. (VHF Reflector)

ARNEWSLINE FUND REPORT: THANKING OUR AUGUST SUPPORTERS

Ladies and gentlemen, with the August listener appreciation list, here is Amateur Radio Newsline support fund administrator Andy Jarema, N6TCQ.

--
In the month of August we heard from:

Mt. Beacon ARC of Wappingers Falls, NY; Benton Bonney of Orlando; Hiram's Hams Amateur Radio Society of Miami.

A BIG thank you to Roy Blanchard, N5YHS of New Orleans; Mike King, W5PY of Slidell, LA; Daryl Stout, N5VLZ of Little Rock, AR; Robert Guidas, KB4ABF of Maynardville, TN; Radio Amateur Club of Knoxville, TN; Richard Wolf, WI8X also of Knoxville.

Monthly contributor Frank Hemko of Harrods Creek KY; Robert Majkrzak, KA8WQL and Cheryl Turner, KB8YKA of Berea, OH and Wally Willhard, W7MVK of Bountiful, UT.

From California, William Walters of San Jose; Daniel Hart, KE6UHG from Bakersfield; Robert Vitzelio, W6AEJ of Downey; our friends at the Pasadena Radio Club, W6KA and our old friend and star of last month's QST Magazine, Dave Bell, W6AQ of Hollywood.

Andy Jarema, N6TCQ. Thank you for your support.

--

More with Andy and the support fund in future newscasts. (ARNewsline Support Fund)

**

INTERNATIONAL - GUATEMALA: A BIG UHF WIN FOR HAM RADIO

A big win for ham radio in Guatemala. The Club de Radioaficionados de Guatemala says that nations spectrum regulators are returning the 430 to 440 MHz band to Amateur Radio use. Amateur Radio Newsline's Bill Burnett, KT4SB, reports from Miami.

--

It was five years ago, back in 1996, when the Guatemalan government suddenly banned hams from access that spectrum. Guatemala then auctioned those frequencies to commercial operations.

But reports out of Guatemala soon said that the reallocation was not working they way the government had envisioned. No reasons were given. Now comes word through AMSAT that these new users will be moved elsewhere and the 430 to 440 MHz band will be returned to its former use in Amateur Radio operations.

And in the hope of preventing this kind of an arbitrary reallocation from ever taking place again, the Guatemalan national Amateur Radio society says that it will ask the International Telecommunications Union to add a footnote to its table of allocations at the World Radiocommunication Conference 2003. One that will give the Amateur Radio service primary status from 430 to 440 MHz in that country.

From Miami, I'm Bill Burnett, KT4SB, reporting for the Amateur Radio Newsline.

--

The Club de Radioaficionados de Guatemala had petitioned the Guatemalan government to reverse its decision removing ham radio operations from the 70 centimeter band. (ARRL, AMSAT, Q-News, CRG, others)

**

INTERNATIONAL: BIG VK SITE FEES WIN

Hams down-under in V-K land are also celebrating after surviving a threat. This, to their use of several key repeater sites. Q-News Graham Kemp, VK4BB, has the details from Melbourne Australia:

--

Rob VK2MT reports on APC News that local clubs were faced with annual site bills of up to $3000. A lot of "e" and snail-mail correspondence was generated plus a couple of visits to Members of Parliament, both at the State & Federal level. What became obvious after about a month, was that the "softly-softly" approach -- while still holding a big stick -- was perhaps the

way to go.

Well, just over 3 months later and the dust has settled. Illawarra have been officially informed that there will be a maximum figure of $300.00 attached to each existing Amateur Club that has equipment at a TransGrid site. Also, they won't be charged per antenna -- as was going to be the case, all existing and documented by TransGrid antennas will be part of the deal.

For Q-News Australia, Im Graham Kemp, VKBB, reporting for the Amateur Radio Newsline.

--

Clubs will have to satisfy several provisos, such as insurance, priority of commercial users and the like. Overall though it is a satisfactory outcome for amateurs and clubs, who could have faced fees ten times as much. (Q-News)

**

INTERNATIONAL - JAPAN: WRTC-2002 AT HAM FAIR 2001

According to a recent WRTC press release, Yaesu will be the principle radio equipment supplier for WRTC 2002. This as WRTC representatives Martti Lane, OH2BH and Dennis Motschenbacher, K7BV sign a major sponsoring agreement with Jun Hasegawa, president of Vertex Standard Co.Ltd. Vertex Standard manufactures the Yaesu line of ham radio gear.

Lane and Motschenbacher signed the agreement while in Japan to represent WRTC 2002 at the recent "Ham Fair" in Yokohama. While at Ham Fair they invited Tack Kumagai, JE1CKA to act as the WRTC 2002 representative in Japan. Kumagai has accepted the post. (WRTC-2002 Press Release)

**

DX

In DX, yet another successful super low frequency report across the Pacific. Jeramy Boot, G4NJH, has more:

--

Low frequency signals have crossed the Pacific for the second time. During the Autumn equinox on the 21st of September, a number of New Zealand and Australian stations sent extremely slow Morse on their 165 to 190kHz LF band. Part of the signal from ZL6QH was received by VE7SL in south-west Canada just before his dawn, fading out some three minutes after sunrise. The path length is estimated to be 11,709 kilometres.

Radiated power was estimated to be 5 watts and the antenna was a long wire at the Quartz Hill club station, which is run by the Wellington Amateur Radio Club. Reception of a complete callsign is the next challenge. The short duration of the opening means that a faster mode must be used, but this is likely to worsen an already marginal signal to noise ratio. Permission is also being sought for ZL6QH to operate in the 136kHz band
--

Because of the extremely slow speed of the contact there is no audio to share with you. In fact, reception requires a computer and a special decoding program. Our thanks to Bob Vernall, ZL2CA, for much of the information on this historic radio event. (ZL2CA, RSGB)

**

THE FINAL ITEM: BANDPLANS ARE IMPORTANT TO THE FCC - PART 2

And finally this week, we take another look at the FCC's position on voluntary bandplans in the Amateur Radio service. According to the Special Counsel for Amateur Radio Riley Hollingsworth there are two kinds of problems the FCC sees. The first is the operator who simply does not know that a specific bandplan exists:

--

"Now, in the first case, not knowing about the bandplan. Thats more understandable than you might think at first. Unless an oprator really keeps up with Amateur publications including League publications, they wont know about the bandplans."

"Now, a lot of operators have a list of frequencies on which they are authorized to operate and they keep it right at the operating desk. I'd recommend having a second sheet with that frequency list that describes the bandplan for each band. In some ways the bandplans are more complex than the frequency list, but in fact they don't really inconvenience anyone and they really do enhance Amateur Radio and make it a lot more interesting -- and make it possible to do a lot more experimenting."

--

But what about that small but vocal group of hams who simply refuse to abide by bandplans by claiming its their right not to. For these people, Hollingsworth has some words as well:

--

"That attitude is very destructive, and they just can't stand it that there just might be an area where they just should not go because of a bandplan."

"Now, they do not stop to think that QRP or PSK-31 could not exist without bandplans. The fact that they have about 3,850 other desecrate frequencies, and don't have to bother the folks in the bandplan set-aside segments -- for example on 160 meters in the CW bandplan recommended segment -- that never occurs to them."

"And of coarse if they were adhering to a bandplan and someone bothered them, they would be the first to knock on the FCC's door."

--

As Hollingsworth stated last week, these are hams who are totally focused on rights and could care less about responsibilities. They do not care about the damage that they do to Amateur Radio and do not have a clue as to how much pressure is on our frequencies from entities that would like to see them taken

away. (RAIN)

If you have absolutely no room for any ground system, any antenna is
better than not being on the air.

My point is that all these claims of no radials needed with high
performance are false, unless the antenna is well over 1/4 wl tall.
There is no free lunch.

20dB is a big compromise. I'd bet something better could be done in
almost any situation.

==========

When NOT over a perfect ground the 1/4-wave loses more than the
5/8-wave because the 1/4-wave radiation resistance is considerably
smaller.

So in the real world and a lossy ground the 5/8-wave has an EVEN
BETTER PERFORMANCE than the 1/4-wave.

However you do need a bottom loading coil. See program BOTLOAD for
coil micro-henrys. See program SOLNOID2 for number of turns.

Wes,

The problem is you and I have no idea what is actually being measured,
and your test will not help.

One glaring problem is with a "floating load resistor" Cecil measured
common mode currents. While it is possible he saw defection on the
scope, it is impossible to have significant common mode currents into
a small floating load because the common mode impedance of such a
load is very very high. He most likely is reading differential
volatges reather than common mode current.

Picture the problems of having an unbalanced winding on toroid
surrounding an unshielded balanced line, with that toroid coupled
through a cable to a unbalanced scope.

The way I would test that setup is to use a small load resistor and
check for deflection on the scope. If I saw noticable deflection I
would know the test setup was flawed in some significant manner.

The next logical test would be to calibrate the pickup for pure common
mode, so I could determine how much common mode current I had.

Frankly, no one who wanted an accurate measurement would clamp a
toroid over a balanced line, and connect that toroid to a scope or any
other large conductive object. That is an invitation for measurement
errors. Balance and shielding problems with a setup like that are
enormous.

A person can measure what he wants to measure, if he designs a
properly flawed test setup.

> Odd that they installed one then.

You still have not explained WHY?
You think there is a problem all because of a "fan" . Some radio's have fans,
are they flawed or inferior? Some amps have fans, are they flawed or inferior?
I can list all kinds of equipment that has fans that would fill a couple of
pages but yet you think a tuner shoud not have a fan like it's some kind
of taboo....Go figure.

Still waiting for an explination on why a "fan is bad".

>

From: rock_bustin@yahoo.com
Message-ID: <879bfb06.0110051022.1dffca4e@posting.google.com>
Source record: 156565

Greetings,

You can see by the title of the post that I only ask the easy
questions.<grin>

I'm out to homebrew an antenna for 160M or 80/160M. Rig is FT-980.
A Heathkit SA-2040 that handles 2KW from 10 - 80 great. Won't quit.
The layout is my yard. Max. vertical distance = approx. 60+ feet.
Perhaps 100+ feet horizontal if dog-legged. Towers are not an option.
Must be a homebrew. Am willing to learn something new (I actually
enjoy it!), but I'm not an EE either, so have mercy.

Have given some thought to inverted "L" but not sure. Am curious:
Is an Inverted L really omnidirectional?? Seems like it wouldn't be
because it's dog-legged in some horizontal azimuth. Thoughts?

Any hope????????

Pointing it straight up with the longest element reflector as far off the ground as you can easily get it will give you a more reasonable measurement. Even then the frequency will read low. The loading of ground 3 ft away is severely affecting the measurement.

Do not cut anything off until you have tried it near the final height.

Aloha,
John KH7T

Do nothing until you test it properly. That close to the ground, all bets are off.

Method 1:

Put the antenna as high above the ground as you can get it, preferably at its final operating height. Then check for resonance, etc. The higher the better, but remember that driving point impedance of the beam depends on its height above ground. If raising it moves the desired frequency in the right direction, that is a good sign.

Method 2:

Not as good as 1, but much better than what you have done already. Mount the antenna boom vertically with the reflector closest to the ground and as high above the ground as you can conveniently get it. In this position you will get a much better indication of the beam's tuning, etc.

But remember, nothing tells the truth like what it does in its final position. And don't believe everything you see from an antenna analyzer unless it is a quality instrument that you have cross-checked to confirm its relative accuracy. For example, what does it measure the impedance of a Cantenna dummy antenna (or any other known good dummy load) to be on 20 meters when connected with only a few inches of coax?

I ran a 204BA for a couple of years in the 70's before we ran out of sun spots and it was a vast improvement over the TH6DXX that I had up previously.

Good luck!

Since our interest in finding Zo is to find the value of terminating resistor that matches the E/I ratio of the foward wave at the termination point, test 1 has a certain direct applicablity. If we examine the source of calibration errors, it is mostly about the RF quality of the termination, measurement of the resistor at DC and assumption that it's behavior at RF is identical.

I think that these will all be small, but why not try terminating the cable in test 1 with a 1/4W resistor of 100, 110, 120, and possibly a combination for 105 and 115 ohms and seeing what the results are. If the TDR test says that 110 or 115 is a better termination that 100, I would go with that rather than the results of test 4.

The value of test 2 is as a simple estimator, and if you are able to get better evidence that test 1 results are more likely than test 4, test 2 might be a good first estimator. I will try some calcs on published cable data to see how closely my method (test 2) estimates the specified Zo of some commercial cables (I am expecting that velocity factor will be a parameter that is directly measured and accurate for published data since it is so critical to cutting of phase calibrated cable assemblies).

>Still waiting for an explination on why a "fan is bad".

I'm not sure if that is a troll or not, but let's pretend not.

Fans aren't always bad. They have their place.

Of course we all know tuners are not radios, with hundreds of watts of
dissipation in a small concentrated area. Amplifiers can have over a
thousand watts of electrical energy turned to heat in a small area.
Obviously both often need fans.

If a tuner does not need a fan, then it is a waste of money. Someone
miscalculated. If it does need a fan, it indicates excessive loss in
some component. Of course the assumption is no one would ever put a
fan in a product where it does nothing, and where it is not needed.

If there is excessive heat, generally that heat would be concentrated
in a small area of an inductor or a small component and the fan won't
do anything anyway because surface area would be too small. Vent holes
would be more than enough.

So naturally, it raises a flag.

Now without a smart or sarcastic answer, what do you suppose the
reason is?

Hi Bill,

Cecil misses the entire point, which is that when an antenna system is involved common mode impedance is an entirely different thing than differential mode impedance. There is very little reason to measure that, it is well established. But if we do want to prove that, we need a test setup that is planned properly.

In this case, something is obviously flawed in the test setup. He read common-mode current when the termination was purported to be a small ungrounded resistor.

I see from a "drawing" he clamped the coupling loop over coax, which went through a balun to a small load resistor.

Assuming the resistor was reasonably small, common mode current would be nearly zero. A floating resistor is not a balanced load, nor is it an unbalanced load. It is a ground independent load that can have any voltage from either terminal to ground, with an extremely high common mode impedance.

That isn't a setup that tests balance or common mode at all.

Any indication on the scope could be from power line RF, tuner case radiation of RF, or any one of a number of other sources. No one who planned this would ever use a scope or other large instrument coupled to a "current transformer" to measure common mode. It is asking for problems.

All that aside, we have no idea what the quantity being measured is. The common mode current can be greatly different than the differential mode current, which is all anyone was saying. Those ratios can be anything, depending on the system.

>Dennis Ferguson

Hi Dennis,

If you consider form of a conductor in loading an antenna, the optimum
form is one that maximizes current over the length of the structure
and minimizes physical conductor length.

It is well established the optimum form of loading for a small dipole
is a capacitance at the ends much larger than the distributed
capaciatnce of the structure, so current flow is uniform. That
maximizes radiation resistance for a given linear dimension.

In that case the inductor can be placed anywhere, so we are left with
the optimum form factor for an inductor. The optimum form factor is
NEVER anything but a round coil with some limits on turn-to-turn
capacitance, and a certain length to diameter ratio that varies with
conductor size and desired impedance of the inductor.

In no case with any of this is "folding back" of a conductor good, it
always results in more system loss.

As for multiband systems, there are many solutions. Every limit can
dictate a different form.

Where the problem comes in is that fractal proponents are looking at
the problems as a form over function. Only a person inexperienced in
RF systems or antenna designs would design that way.

All antennas radiate by amperes over a distance, where the distance is
a linear spatial dimension. If we have a ten foot area linear area
over which the current flows, making the current zig-zag back and
fouth only adds loss resistance.

Now there is an exception when wavelength is long compared to the
distance, because phase can change. In that case folding or bending

the conductor can bring currents, when viewed from one or more specific directions, more in phase (or less out-of-phase) than other directions. There are dozens of ways to do this, and form is not magical at all.

What has happen is people unfamiliar with antenna or RF design have started playing, and found some shapes through accident (or through computer evolution by trying many thousands of shapes) that just happen to do something useful. In other words, the form is selected and then the form establishes the limits of function. Form before function.

The problem is, anyone specifying the random form's results to a competent engineer would see the engineer generally come up with several forms that work.

Designing by form over function is like setting a few thousand monkeys at a keyboard, and letting them type in random characters that a computer rapidly sorts into words. With the fractal designs, it is even less intelligent than monkeys because the computer selects the "designs", tests them, and spits them out.

There is no magic in any shape, rather there are certain rules than any design must follow depending on what you want to achieve. We went through something weird like this fractal psudoscience with something like the rules of nine (I think it was nine) craze in physics. Once in a while reasonable logical science gets tossed aside and the numerologists and soothsayers have a run in science.

It'll mostly pass with time, although there will still be a few stragglers who believe in magic or design-by-accident because they just don't want to learn how things really work.

Tom:

I agree with you. Heh, heh. As you indicated, common mode measurements are not to be trifled with.

Cecil's instrumentation and technique measured something, but probably not what he thought he was measuring. I wonder what the common mode rejection of the power transformer in Cecil's oscilloscope was?

I wonder what... and... at least 10 other such questions...

Common mode supression is not of much interest to most amateurs. Certainly most amateurs do not have access to the proper instrumentation, or training, to effect good quality common mode measurements/engineering. The science/art of common mode engineering is usually left to advanced instrumentation engineering gurus. Folks who design systems with high balance and have to set and meet stringent common mode rejection specs.

I see only three limited areas of concern for amateur radio stations for good common mode engineering practices.

(1.) To eliminate "rf burns" from "rf in the shack" while transmitting. The "ouch the mic bit my lip syndrome"! Most ordinary (non-competitive)amateur station operations as well as competitive stations would "worry" about this problem, but it is easily solved with simple approaches to controlling common mode response, i.e.only a few dB of common mode rejection is required to chase away the rf burns.

Other than keeping the shack from becoming "hot" on transmit, which is a somewhat trivial exercise in common mode engineering, the only two areas that I can think of where extremely high common mode rejection is of interest, and then ony to "competitive" amateur stations involved in weak signal work, would both be on receive.

(2.) When trying to "pull out" very weak far field distant stations, that are being received on extremely directive arrays, where deep array nulls are being used to null out far field QRM/QRN... here poor common mode responses may ruin the deep array nulls, and bury the desired signals...

(3.) When trying to "pull out" very weak far field stations through local QRM/QRN in the near field near the feedline... here poor common mode response will allow the near field noise to bury the weak far field signals.

Would you agree?

Are there other areas of interest to amaterus for good common mode performance in antenna systems?

Tom:

I saw the Palstar tuner unbuttoned at Dayton a few months ago in the Palstar booth.

When I walked up to the table that it was sitting on, I saw a power cord hanging off the back and I said to myself, hmmm....

"That's the first tuner I've ever seen that has an AC power cord!!! I wonder what that's for?"

The top was off, so I looked in and saw the fan. The fan was "pointed at" the balun on the output, I then asked the guy manning the Palstar booth, what's the fan for? He replied, I don't know!

I walked away shaking my head? Heh, heh... a passive network with a power cord!

In their literature or specs, they [Palstar] really need to address the question of the fan, all it does is raise questions and concerns...

What's that saying our software brethern have, "that's not a bug, it's a feature"!

That is certainly one area of concern, although I don't mind a good
set of searing hot lips once in a while. My wife just refuses to kiss
my coax or put her head in the microwave.

Yes indeed, that is another concern.

In my case, I've had arcing problems from the shield of feedlines to
the tower legs through the jackets of cables.

That eventually ruins the jacket of the cable, and it causes TVI.

Hello Richard Clark,

In reality the objective of my thesis was to design a multi-band antenna for mobile communication that could transmit and receive for 4 or 5 frequency bands for mobile phones (including the GSM and UMTS bands). Reading all the stuff from IEEE of Carles Puente and much more thesis and information, when I discovered that the structure of such kind of antenna could changed easily for specific frequency requirements because of the self-similar structure that enhances

multiband behavior the Sierpinski gasket patch antenna started to interest me.

But continuing analyzing this antenna I got a lot of problems which till now aren't solved:

1) Till now I couldn't make simulations that were in agreement whith those published by Carles Puente using the software of HP Momentum which is ADS. The first problem was that because of the complexity of the structure it was very hard to implement that. The problem would lie in the fact that the edges of the triangles which connect the subgaskets weren't connected to each other and therefor the current couldn't flow from the bottom to the top of the gasket. Till now this problem isn't resolved!!!Must there be a path of finite width lying over the edges for the current could radiate in all gaskets??

2) Because of the complexity I was unable to design such an antenna for the requirements because of point 1. Therefor my tutor said to investigate only a two or three-iteration Sierpinski gasket but because of the same problems what to do with the edges the simulations were not in agreement with Carles Puente.

3) Therefore I searched more information for analyzing these type of antennas and searched for other software packages. It seemed that IE3D, Ensemble,FEKO and NEC were investigated already with that kind of antennas.

4) The problem is that all the articles that I have are only based on experiments and the FDTD method. Is that the best method??Why not choosing MoM??Is the structure really so complex that such formulas not exist while for a triangular patch they are known??Can the formulas for the triangular patch be changed when cutting a hole (one-iteration Sierpinski gasket) so that these frequencies can be calculated??

5) Because till now I was very disappointed about my results (I don't have nothing yet) my tutor asked to choose maybe for another solution to write a program in Fortran based on the EFIE method that can be applied to arbitrarily shapes. Is that the convient way for my thesis. Because of the complexity of the problem he lower the weigth of the proyect to only include three bands instead of five. The 1800 GSM band and the two UTMS bands. All these bands seem to lie a factor of 1,09 from each other.

Therefore I ask you if it is really useful to continue with such a complex object (a Sierpinski path) antenna to include these three bands or to make use of more simpler antenna.

Do you know of a configuration of patch antennas that can include these three bands??

Thanks all the people for supporting me because I am really anxious because of the complexity of the problem and the fact that I started

this thesis last year in november having no good result.

P.S.Is it possible that you send me a copy of the EZNEC-file of simple Sierpinski gasket so that I can use it for experimenting for my thesis??

Another method of measuring Zo is to terminate the line with any resistance in the same ball park as Zo (there's no need to know what its actual value is) and then measure input impedance versus frequency, at fairly close inervals, over a wide enough frequency range to get a few peaks and troughs on a graph. Draw a straight line through the middle of the graph and there you have it.

You need a longish length of line, several wavelengths long at the highest measurement frequency. The longer the line the more accurate the result.

You will also have the velocity from the frequency difference between successive peaks and troughs in the graph. Smoothness of the plotting points will indicate how much confidence can be placed in the results.

When measuring stuff like zip cord and speaker cable, samples which appear to have the same dimensions may differ in impedance because permittivity of the insulating materials may differ. Personally I favour the clear insulation. I don't trust dense colouring pigments.

Reg.

Geesus H... A+ for effort.

Those various measurements and calculations are all probably well within their respective error bounds. Do the math again - this time bring the "+/-" error bounds along for the ride (start to finish). If something still doesn't line up with the others, then perhaps there is a Nobel Prize in Physics waiting in there for discovering a new and improved formula or unknown physical effect (probably not).

Thanks for trying my suggestion. This is fun...

Well, that's a little wierd -- on the Palstar web page they say, "10 Amp
edge-wound solid copper silver plated roller inductor, FAN cooled." So why would
they point the fan at the balun?

|>
|>
|>I should clarify my badly constructed last sentence. My concern with
|>non-linearity is in the balun, not the relationship between Z and I.
|
|Wes,
|
|The problem is you and I have no idea what is actually being measured,
|and your test will not help.
|
|One glaring problem is with a "floating load resistor" Cecil measured
|common mode currents. While it is possible he saw defection on the
|scope, it is impossible to have significant common mode currents into
|a small floating load because the common mode impedance of such a
|load is very very high. He most likely is reading differential
|volatges reather than common mode current.

I was not and am not addressing whether Cecil should be seeing any common-mode
current when he terminates his cable with a balanced, resistive load. I was
addressing whether or not his test setup was understandable. To me it is,
albeit less than ideal.
|
|Picture the problems of having an unbalanced winding on toroid
|surrounding an unshielded balanced line, with that toroid coupled
|through a cable to a unbalanced scope.

I can picture that, but that is not what Cecil drew. His line is coax.
|
|The way I would test that setup is to use a small load resistor and
|check for deflection on the scope. If I saw noticable deflection I
|would know the test setup was flawed in some significant manner.

That assumes that all agree that there should be no common-mode current when the line is terminated with a balanced, resistive load; a fact not in evidence.
|
|The next logical test would be to calibrate the pickup for pure common
|mode, so I could determine how much common mode current I had.

That of course is good logic but almost impossible to do. See below.
|
|Frankly, no one who wanted an accurate measurement would clamp a
|toroid over a balanced line, and connect that toroid to a scope or any
|other large conductive object. That is an invitation for measurement
|errors. Balance and shielding problems with a setup like that are
|enormous.

Again I point out that Cecil's setup was coaxial.
|
|A person can measure what he wants to measure, if he designs a
|properly flawed test setup.

Indeed. However, Tektronix and HP both manufactured both active and passive current probes to be used with their oscilloscopes. I have used them into spectrum analyzers. Once again I cite Roy's paper for an example of just such a passive probe. His is improved by the addition of a balun on the secondary winding, but in theory if there is zero capacitive coupling between windings, this would not be necessary. This is no different from a power transformer that isolates a ground referenced power line from a floating load.

The problem with Cecil's setup from my perspective (again ignoring whether there should be any CM current) is the fact that the "common-mode impedance" of his "single wire" transmission line is really the differential-mode impedance of a two-wire unsymmetric line where the second "wire" is earth and surrounding objects.

For any repeatability, the test needs to be performed with a coax line suspended horizontally at a fixed height over a quasi-infinite ground plane. Also, *nothing* is allowed to change except for the termination resistance. This odd-mode line is afterall not matched at either end and will operate with standing waves. (The input end is grounded, the output end is open)

This is also why I submit that "calibration" of the probe, at least in situ is for all intents, impossible. It can be calibrated in a seperate setup, but since there will be standing waves on the line, the absolute reading will depend on the frequency, line length and position of the probe along the line.

73,

Wes N7WS

Does the air discharge from the front or the back of the fan blade? Maybe
the front was pointed at the balun but the rear was pushing air over the
coil?

I guess the next step would be to do like the "big boys" and wind the coil
out of tubing through which cooling water is circulated! That should really
sell in W6-land.

I did use the differential inputs on my O'scope. I have an X-Y position
and a CH-2 INV position that gives X+Y. The RF was indeed my 7.1MHz RF.

I used the differential inputs to my O'scope. Reversing the

leads made very little difference. With the leads shorted
together and RF power on, RF was barely detectable. It was
not a super accurate measurement but did seem to indicate a
trend.

The scope has balanced differential X,Y inputs. With both leads
connected to the same point on the pickup loop, the deflection
was negligible with RF applied.

> Frankly, no one who wanted an accurate measurement would clamp a
> toroid over a balanced line, ...

The toroid was over an *unbalanced* coaxial barrel on the input
(unbalanced) side of the balun as indicated in the diagram.

One can infer from what you said that common mode currents remain
constant, i.e. "unrelated, as the differential impedance is varied.
Is that really what you wanted to imply?

> the purpose of a choke balun (as described) is to reduce(choke) common
> mode currents, why is the Balun there at all?

To show that when the balun is operated into its designed-for load,

common-mode currents can be lower than when the values of the load

impedances are increased.

> The original comment this is all about was about impedances, not
> currents, so- why the claims about currents being effected?

Do not the impedances effect the currents?

It's still pretty omnidirectional. There is a bit of gain broadside to
the horizontal wire. The pattern is bidirectional, but the gain is not
too high, so I still consider it a fairly omnidirectional antenna. The
taller the vertical part, the more omnidirectional the pattern. If you
use a T vertical, the pattern will be even better " more like a normal
vertical" with little horizontal componant. But depends how far you
want to talk also, which will be better. The L might be better for
close in stuff, but the T would be a better DX antenna. I've been
using a Z dipole for a couple of years for close in stuff. It's pretty
good for that, but lousy for DX. An inv L or T with a 60 ft vertical
section will be pretty good if you use the appropriate number of
radials for a ground screen. MK

The grounds for the two X,Y differential scope leads were connected
to the coaxial barrel around which the toroid is wrapped. Was that a
problem?

The resistor(s) were not small. They are 600 ohm 50w non-inductive
resistors each of which is four inches long. The wires from the
banana plugs on the balun output to the resistors were about three
inches long.

245. Creeping VF? (Offshoot from 75-Ohm twin-lead)

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-06 05:59:42 UTC
From: "Dan AC6LA"
Message-ID: <i5xv7.18233$ev2.27984@www.newsranger.com>
Source record: 156498

Jack Smith says...
>
>I've spent a second interesting morning in the workshop pursuing the
>elusive Zo of zip cord.

<snip an amazing set of tests>

Jack,
Just to add some fuel to the fire, there are also a couple of other ways to determine Zo which are derivatives of what you've done.

1. Zo = 1016.703 / (CpF * VF)
where
CpF is the capacitance of the line in pF/ft
1016.703 is just the reciprocal of the speed of light constant 983.5711 (MegaFt/sec) with the decimal point moved to allow CpF in picofarads.

This equation is found in the "Complete Coaxial Cable Catalog and Handbook" by Times Microwave. It is also used by Witt, "Transmission Line Properties from Measured Data," ARRL Antenna Compendium Vol 6, pg 184. Using your data I get
Zo = 1016.703 / (20 * .662) = 76.8

2. A second technique (a derivative of the sqrt(Zoc*Zsc) method) is to terminate the line with a load resistor (ZL) approximately equal to the estimated Zo, then measure the Z at the input end of the line at a frequency which represents 1/4 wavelength (Zqtr). Then
Zo = sqrt(ZL * Zqtr)
The exact frequency is not critical because the input impedance will change very slowly with a change in frequency, since the termination is approximately Zo. A DMM may be used to measure ZL.

Both of these techniques can be done with the simple test equipment that I have, namely a capacitance meter, a DMM, and an antenna analyzer (Autek, MFJ, etc) to measure a Z magnitude value.

However, you mentioned in your post...
>(d) Measured Vf using the following technique. For two different
>lengths of zip cord, using a homemade test fixture and an HP8754A
>network analyzer, I measured 1/4, 1/2 and 3/4 wave transmission
>minima. The result of these six measurements is Vf = 0.662 +/- 0.015.

By any chance did you see a pattern in the calculated VF's as deduced from the 1/4, 1/2, 3/4 wave frequencies? A while ago I measured the VF for a length of RG-58 (solid polyethylene dielectric). The physical length was 37.875 feet. The termination was a "nearly perfect" short (braid and center conductor twisted together and soldered). Of course a short at the load transforms to a sharp Z peak at the line input at the 1/4, 3/4, 1 1/4, 1 3/4, etc. wavelength

frequencies. Using an Autek analyzer I measured Z peaks at frequencies of 4.193, 12.63, 21.12, and 29.62 MHz. These display readings were verified by listening to the output of the analyzer on a general coverage receiver of known accuracy. Unfortunately, these numbers result in a small "creep" in the deduced VF, as follows:

Freq WL VF
4.193 0.25 .646
12.63 0.75 .648
21.12 1.25 .651
29.62 1.75 .652

I never figured out why this was happening, other than to vaguely wave my hands and say that it must have something to do with a) stray L and C in the analyzer, b) harmonic content of the analyzer output, or c) re-reflection from the analyzer back to the line. However, if you saw a similar pattern using a piece of test gear that is several orders of magnitude more expensive than what I used, then something strange is going on.

So, do any of you gurus who know the circuit details of the Autek or MFJ analyzers have any theories? If these VF numbers are correct (a big if), it would imply that the dielectric constant changes from 2.396 at 4 MHz to 2.352 at 29 MHz. That can't be right. Isn't the dielectric constant, well, -constant-, at least over a limited frequency range such as this?

I'm stumped. Any explanations greatly appreciated.

73,
Dan AC6LA

Dunno, I think you can if if you set it up right. With modeling, I found 3/4 wave radials, at a 45 degree slope gives the appx textbook gain values. With the steep radial version with 5/8 radials, the gain was about 4.2 or so dbi, and the pattern was very good and clean. It's using 5/8's with 1/4 wave radials that is the mistake. Also in my case the 40/17 combo cost nothing. All built from junk antennas. I converted a heavy duty 5/8 CB antenna, and adding tubing within the tubing to make it stronger, and got very skinny at the top. The tip section was a car antenna whip. So it was light and totally self supporting. Was it worth it? For 40m DX it was the best antenna I've ever used here on my limited lot. it won't beat a beam or an array like a bobtail curtain, but it will beat about everything else.And the same applies for 17m. It was the best out of 3 or 4 antennas. On 40m at night the difference between my dipole at 36 ft and the GP at 36 ft, was 4 S units in favor of the GP when working long DX. I've also tested all the common verticals on 10m, and the 5/8 GP with 3/4 wl radials won every time over all other versions when I compared them. "1/4 gp, 1/2 wl verticals, etc. Where a 5/8 GP is usually lousy is on 2 meters. Mainly because everyone insists on using 1/4 wl radials. I'm convinced if you built a 2m GP using my enhanced steep 5/8 radial design with proper decoupling, the story would turn out differently. But like I said in the other post, that approaches being a dual 5/8 collinear. Using the modeling, I decided 5/8 wave radials are better than 3/4 wave. 1/4 wave radials for a 5/8 antenna are a joke, and should be used only as a last resort. BTW, all these examples assume an elevated antenna, not ground mount. MK

>
> Any opinions out there on either one of these systems? The 3 band
> vertical idea is from the "low band
> dxing" book and the inverted L from an old QST article.

Either one would work. The L's would be more efficient being they need
no loading coils. A 3/8 L will have much horizontal componant, and
while good for general use, the dx performance will suffer over a
"clean" vertical. But a 3/8 is good in that it reduces ground losses.
If you used the 78 ft vertical, and had a way to attach top loading
wires that would be good. Even coil loaded, it would be ok being that
tall. But it would be better to use loading wires if possible. This is
where the inv L's work out nice. They don't need a lossy loading coil.
A 1/4 wl inv L would have a better DX pattern than the 3/8 wave
version. Also consider a T vertical, if you want a good clean omni
vertical pattern with little horizontal. MK

249. Re: Tuner for high power

Tom:

No i'm not a troll. I just wanted an answer to my question, thats all.
In your last post I didn't get one so my response was to pry a little
bit to get an answer. And you did so I wont pry or sound sarcastic
any more. Sorry if I offended you. Didn't mean to.
When I bought the tuner I didn't care if it had a fan in it or not. I
bought the unit based on another hams recomendation who
has "tried them all" so this is what I bought. I almost bought the
ATR300 and it took me a month to decide but I thought I would give Palstar
a try. As for the fan, it is pointed towards the part of the inductor where I
would think most of the heat would be gernerated but in this country probably
would not be required due to power restrictions we have but I think it would be
a different story in some other countries where they are more power hungry.
When I talked with Paul at Palstar he mentioned that he was exporting quite
a few of these units. I wonder if that fan was meant for the export demand to
match the higher power limits. I am sure that fan is not there to cover a
problem, I have allready tested that theory many times without ever having to
turn the fan on. I wish I could test the power theory on a wire but then I would need a
bigger amp and probably would have to move to another country. I also don't think
it is a miscalculation. If it was, I would think the later production runs would have
had them removed.
Even with all this fan controversy I am still very happy with the tuner that I have and
i'm sure that you are very happy with the tuner that you have and that is what counts.
Right?

If someone really wanted to know what's with the fan I suppose they could
call Paul over at Palstar, act like a prospective customer and ask him why does it
have one just to satisfy a curiosity. I'm not going to bother because for me it's just
not that important. Probably get a better answer than the person at the booth
at Dayton that was more than likely a hired hand.

Start simple and add complexity - not the other way around. There is
not much point in going beyond the 2nd iteration for Koch Quadratics
or 4th iteration for Sierpinski's.

A real problem: trying to describe a fractal in print is insane. Give
me a graphics page you can post on the web or email.

Be explicit, name the actual 5 band frequencies. They sound like they
are grouped closely by your description. You fail to state the
antenna's overall size constraints. You do not state the goal. Do
you want to focus on matching characteristics? Radiation
characteristics? Both? For all 5 bands!?

You state you have problems, but you do not describe them. Give the
details. Tell us what characteristic Puente reported and what you
observed in your work. Make it simple.

>
>Therefore I ask you if it is really useful to continue with such a

>
>Do you know of a configuration of patch antennas that can include
>these three bands??

review the resonances offered in HF, found at:
http://members.home.net/kb7qhc/antenna/fractal/Constant%20Height%20Comparisons.htm
and see if there is a design that presents resonances in the same
ratio of frequencies as your bands above. If you find a design with
the same ratios, simply scale it to those frequencies. You have to be
very careful to pay attention to scaling the wire diameter too. One
caveat, it is highly unlikely you will find the magic combination of
fractal, ratios, and scaling for a works out of the box first time
solution (it's a cruel world). Odds are good you will get a near
solution.

The simplest solution is to design a Large fractal. You can cover as
many bands as you want if you think Hi-Z and in dimensions of 3 to 10
wavelengths. A very large 2nd order Koch triadic spans 25 MHz HF/VHF
well below 2:1. This is an incredible fantasy at HF because it would
be a 64 meter tall structure. However, as your application is some
two orders of magnitude smaller, this model of the sierpinski would be
64 centimeters tall - if that qualifies as a patch, then have at it.
>

Hi Rafael,

I browsed my work and found I didn't do much with the Sierpinski at my
pages except for:
http://members.home.net/kb7qhc/antenna/fractal/Constant%20Fractal%20Comparisons.htm
which show the broadband SWR sweep for iterations 1 through 6. As
I've got a warning that this page is under construction, it is
tentative in nature, but the data will be consistent. I will rummage
through my hard drive and post you plenty of Sierpinskis. I don't do
many loops so you may have to do some cut and paste - shouldn't be
hard.

More tomorrow morning.

Date: 2001-10-06 11:38:15 UTC
From: Jack Smith <jsmith@mnsinc.com>
Message-ID: <k4qtrt0fp1f076egq4tr3pgejdi13ufbnv@4ax.com>
Source record: 156506

Dan:

Thanks for some additional suggestions, and I'll give them a shot this morning.

Here is raw Vf data:

Frequency Vf
9.5 0.668
18 0.632
18.1 0.637
28 0.657
37.2 0.652
57.1 0.668

If you plot these, and exclude the first data point, there is a clear trend towards increasing Vf with frequency.

The frequency data is from the HP8754A network analyzer. It has a 1 MHz crystal marker option, and I was using a sweep that allowed me to read the frequency within 100 KHz or so.

Assuming that the change in Vf is not measurement error, I suspect that the dielectric constant of the vinyl insulation changes with frequency.

Incidently, I was poking around the internet this morning and found an on-line transmission line Zo calculator at:
http://www.mogami.com/e/cad/electrical.html

Here is the output when I ran the zip line through it. (I agree with the Zo; measured C 65.6 pF/m, measured L at 1 KHz = 0.648 uH/m.)

electric characteristics of twin-lead:
diamter of conductor: 1.22 mm
conductor spacing : 2.74 mm
di-electric material: PVC

capacitance 59 pF/m
inductance 0.70 uH/m (DC)
inductance 0.60 uH/m (HF)
characteristic impedance 101 Ohm (HF)
velocity rartio 0.56 (HF)
attenuation 0.005 dB/km/sqrt(frequency)

Notes:

1. These value are approximation.
2. The attenuation is based conductor loss only.
3. These vales may vary with composition of compound for PVC
insulation.
4. use "wire-gauge computation" for DC-resistance.

254. Re: Creeping VF? (Offshoot from 75-Ohm twin-lead)

Source record: 156509

The velocity factor of ALL lines naturally increases with
frequency. It does not result from a decrease in capacitance as
frequency increases. Capacitance is the only parameter which
remains constant.

The series impedance of any line is R+j*omega*L. In view of the
shunt capacitance it is intuitively obvious that R has the effect
of reducing velocity. And R increases with squareroot of frequency
due to skin effect.

However the series reactance omega*L increases faster than R and is
proportional to frequency. The effect of R is swamped by omega*L.
The overall effect is an increase in velocity with frequency. Only
at infinite frequency does velocity achieve the free space velocity
of 1 / Sqrt(L * C). However, at a few hundred KHz most of the
increase has already taken place.

Mathematically -

VF = 1 / FourthRoot(x squared + 1)

where x = R / (Omega*L) = ratio of resistance to reactance.

There is another factor which increases velocity with frequency -
the inducatance L decreases with frequency. This is also due to
skin effect.

Line inductance is the sum of that external to the conductors plus
the internal inductance. Inductance is a maximum at DC where the
whole of the conductor cross section is involved. But as skin
effect begins the center of the conductors is ineffective.
Eventually, at HF, the conductor is just a thin skin and most of
the internal inductance has vanished. What remains gets still
smaller as frequency increases and so velocity tends to increase
even at VHF.

Use program COAXPAIR to see how VF behaves versus frequency. Enter
F = 10 MHz and VF = 0.66. Then reduce frequency.

At audio frequencies on a line something like RG-58 the velocity is
about 1/7th of the free space value. At power frequencies is about
1/30th of free space.

On open wire lines everything happens just the same but at lower
frequencies

Regards, Reg, G4FGQ

Free radio software.

Tom, I don't have that article, but was there a comparison to the
Hy-Hain what is it 18AVQ? That's the one with the good sized tower that
has the stubs for multiple band operations. I wonder what it would do
for him with a decent concrete block UFER under it and what he could do
for even short radials .. as compared to the Gap Titan figures above.

Of course there are other variables as well in doing this, but, in
concept, wouldn't that be a better bet for him? I know a number of hams
locally here in Central Texas who have done quite well even on 80 with
this antenna on city lots and less than full length radials under it,
plus have really decent results on 40. Tom Comstock, N5TC, the ex-West Gulf
ARRL director from here over many years, actually had a really good run
at DX life with that and a fairly small tri-bander. His collection of
every single one of the deleted country cards with this setup, from work
over many years .. was quite fascinating to see!

From what I've seen of even full sized poles set in just concrete with
re-rod laced ground support, that's better than Gap or any of that
stuff .. at least in practice, it seems.

--> Sleep well; OS2's still awake! ;)

> --
> cheers, CAM, W5DXP
[snip]

Thanks Cecil, that's the scope's differential input CMRR, *wow 26dB at 1kHz*. Hmm... not very high! 75dB would be better especially if it was at 10MHz. But 26dB at 1kHz is not unusual for scopes. Scopes have notoriously low CMRR's and longitudinal balances.

What is the Leader's differential input CMRR at 100kHz, at 1MHz, 10MHz, 30MHz? Specifically at the frequency you measured? What is the Longitudinal Balance of the Leader's differential inputs as a function of frequency? Specifically at the frequency at which you made the measurement? What is the effect of the CMRR and Longitudinal Balance on your measurements? The longitudinal balance and the CMRR are two different but inter-related parameters, both strong functions of frequency, etc...

Cecil my earlier question was not even about the differential vertical inputs, I was deliberately trying to take a devils' advocate role, and I was really asking about another second order effect, the CMRR at the power supply input, 110VAC lead from the AC mains of the Leader. i.e. If you insert a common mode signal [at the frequency of interest, say 10MHz] on the AC mains plug of the scope while it is operating with the usual lead and cable dress configuration, what is the deflection on the scope's vertical trace at maximum gain? etc... etc... etc...

Your efforts are commendable, but probably not accurate, since as Tom advises, a sensitive and accurate common mode measurement setup needs a lot of thought and planning and knowledge of the common mode rejection and longitudinal balance of all of the instrumentation and interconnecting wires, cables, impedances, etc... This is usually very difficult because most of the common mode impedances of interest are not on any schematic diagram and are not specified or controlled by the design of common instrumentation, and the usual haphazard control and management of cable layouts, etc...

All this to say, thanks for the efforts, but I remain skeptical of your measurements.

But... but... folks... I thought the original question being addressed by
Cecil and Tom, was...

"Is the common mode impedance affected by the differential mode impedance?"

i.e. does the common mode blocking impedance of a common mode choke have
anything to do with the differential impedance of the line on which it is
installed?

Cecil said yes, Tom said no.

What?

Peter, have you read, "Baluns: What They Do And How They Do It"?

How much choking impedance does one need to "encourage" the current
to flow into one leg of a dipole instead of back down the outside
of the coax? Isn't that choking impedance related to the impedance
looking into the dipole?

[snip]

Yep... I agree... sure is...

That's a flat line situation, no standing waves, and so a choking impedance for a 50 Ohm coax fed 1/2 wave dipole would be just fine if it were say 10 - 100 times larger than 50 - 75 Ohms, say 1000 Ohms or more... but where should it be installed to be most effective? At the antenna feedpoint? 1/2 way down the line to the xmtr? At the xmtr? Does it matter where you put the choke? Are two separate 1/2 value chokes better than one? If so how far apart should they be spaced? If two are better than why not 3 or 4?

Now to the point that I thought Tom was addressing a thread ago...

How about if the line is not flat? i.e. lotsa standing wave action. Say about a 3/4 wavelength doublet fed by 600 Ohm line where the feed line comes away from the doublet at a 45 degree angle causing lotsa common mode currents on the line. What would be a good common mode choking impedance for that application? Where should it be placed? At a high current point, at a low current point? Where? How many are needed? Does it matter?

I think the latter situation is the one that Tom was thinking of... but mebbe not.

Thoughts, comments?

Hi Dan,

Consider you've nearly changed the excitation frequency by an order of magnitude and the measured DC has shifted less than 2%.

If there is anything to be concerned about, it is the values coming so close to boring repetition. Your equipment is not 2% grade over this wide a frequency range. To imply that much accuracy would require a suite of 5 to 10 readings cross-correlated with known samples.

Resolution is NOT accuracy. The digital readout may roll out the numbers to yield 2.396 and yet be measuring a known sample of 2.445. In other words the meter manufacturer gave you two extra digits (100 counts) of statistical noise to inflate your ego. The only time these extra places of resolution pull your ego out of the mud is when they indicate relative change. Without standards for comparison at each frequency, this particular measure of DC does not have that particular benefit.

Your other input and techniques were right on. They illustrate that accuracy and precision are not confined to the standards lab.

Hi Cecil,

The toroid is wrapped around...?

As the description defies visualization, I would offer you have at
least a 50% chance of a serious problem - unless you put your scope on
a ground buster or powered it through an isolation transformer.

All should recognize that if there is Common Mode problem anywhere,
there is a Common Mode problem everywhere. The measurement of Common
Mode demands that you have to measure without introducing or suffering
from Common Mode. A "small" floating probe with indicator is the best
of all worlds; however, as soon as you plug it into the wall - all
bets are off.

Still and all, it is unlikely your probe (as I've understood it to
this point) introduces a CM path or suffers from CM currents. By my
estimation, your probes choke that to about 10K. This is true only if
the scope ground and the system ground are not co-mingled.

Peter, K1PO wrote:
"Does it matter where you put the choke?"

Radiation from a straight conductor depends current and the distance it flows. Current on the outside of coax results from conduction and induction. A choke at the junction of antenna and coax minimizes conduction between outside of the coax and the antenna. Induction on the outside of the coax is minimized by distancing the coax from excitation, aligning the coax for least excitation, and making the exterior of the coax non-resonant.

Best regards, Richard Harrison, KB5WZI

What choking impedance is needed for a 1/2WL dipole?
What choking impedance is needed for a one WL dipole?

Yet another day stalking the wild Zo of zip cord.

I've posted the graphics associated with this discussion on my web page at

http://home.cox.rr.com/k8zoa/Zip_Cord_Zo.htm

As suggested by Owen Duffy, I revisited the TDR measurements with fixed resistors. What I found makes more sense now. The Zo is very close to 100 ohms. And, using a small trimpot, I got a consistent value of 102.3 ohms. I'm baffled as to how I came up with 114.8 ohms yesterday. It might have been something as simple as hand capacitance or perhaps even my fingers contacted the end of the line then. To avoid that today, I used a fixed clamp to hold the end of the line in position.

I've posted some fuzzy photos of the TDR screen for open, short, 91 ohms, 100 ohms, 110 ohms, 120 ohms and 102.3 ohms on the web page.

I also made a series of 85 driving point |Z| measurements as suggested by Reg Edwards. To meet the requirement of the line being electrically long (several wavelengths), I had to use a much higher frequency than I used in any of the earlier tests. Hence, I'm not sure it can directly be compared. The web page plots |Z| versus frequency from 105 MHz to 220 MHz for the 17.3 ft line, terminated with 100 ohms. It also plots Vf versus frequency. I don't trust these measurements as much as the lower frequency ones. I hope Reg can cast an eye on the plot and see if it makes sense.

How much would you need for a one wavelength center-fed dipole? :-)

I ran another experiment. This time I used a IN34 to rectify the RF
from the pickup toroid and measured the DC voltage. No o'scope. My
antenna system is resonant at about 36 ohms on 40m with 88ft of
"450" ohm feedline. Adding feedline to that 88ft results in inductive
reactance. With the coax driving a 50 ohm dummy load, the voltage
reading was virtually zero. Frequency was 7.1MHz. Power into the
tuner was nine watts.

XMTR---tuner----pickup over coax----balun---450 ohm line-----dipole

Feedline length DC voltage from the pickup loop
86 ft 1.5 volts (slight capacitive reactance)
88 ft 1.0 volts (resonance ~ 36 ohms)
92 ft 3.2 volts (inductive reactance)
100 ft 6.0 volts (more inductive reactance)

It continues to seem clear to me that operating a balun into a
high differential impedance when it was designed for a low
differential impedance actually *causes* common-mode problems.

Hello,
I am trying to find some plans or ideas for a remote location, roof mounted cell antenna that has TX Rx 830 850 mHz for my audiovox digital cell phone. I have another " internal antenna" that will adapt to the phone from RG 58 etc.

Help please

Craig M Bereznoff

Again Jack, my compliments to you for some wonderful work.

I viewed the TDR shots with interest. It strikes me that the critical moment when a reflected wave is detected is at 6.15cm on the graticule. It appears to me that the 110 and 120 ohm loads go closest to 'freezing' the voltage as it was at the instant the reflected wave arrives back in the other test runs.

Although some think that we are splitting hairs, the measurement techniques and the results are really usefull in validating (or invalidating) some simpler methods of producing practical estimates.

Interesting thing is that some of this was driven from my comment that this stuff is not very close to 70 ohms, and that if you want to use a tuned line, you might be better off using ladder line or even TV ribbon (subject to power handling of course - which is not such a problem here in VK). We also have a better understanding that the cable referred to in the publications has fairly thick conductors. In VK, we generally use a 240/415V 3 phase power supply for appliances, and most high power appliances (demanding a 15A rated cable) will have an integral earth conductor and be 3, 4 or 5 cores depending on the number of phases and whether a neutral is connected.

The largest single insulated flexible twin lead 240VAC rated that I have seen in VK is 0.75 sq mm which uses 1mm diameter conductors (24/0.2) spaced 2.7mm c/c. We do have red+black twin cable for vehicular applications, and although it is available with thicker copper, the insulation is thicker and the spacing increases (eg D/d=3.9/1.5).

I would be interested further in Reg's comments re loss (I think he explained that low Zo parallel lines will have higher loss than coax with an equivalent centre conductor diameter), and how the cable performs when wet or iced... I suspect not as well as ladder line or TV ribbon.

Source record: 156435

Howdy,

The 2-B matching equations sometimes call for 2 caps or 2 inductors if the source and load impedances are not real.

I have a program installed in my HP-48 calculator to figure out the elements. And there always two solutions for each matching task.

> --
> cheers, CAM, W5DXP
[snip]

Well, I still don't see it that way myself.

I believe that a current balun/common mode choke might cause differential impedance mismatches in the differential line in which it is installed, hence reflections and increased SWR along the differential line, say for instance if the Zo of the balun line is different from the Zo of the transmission line, but... it will not cause any common mode problems.

Placing a current balun built of 300 Ohm line with a 5,000 Ohm common mode impedance in a 50 Ohm feedline will not cause common mode problems. It will increase the common mode impedance by 5,000 Ohms, abd it will cause a 50 Ohm to 300 Ohm impedance "bump" for the differential line.

Now if the current balun itself has poor longitudinal balance because it was not constructed correctly, then it might just introduce a common mode problem, but that's a different issue and has nothing in particular to do with the differential impedance. Merely putting a current balun into an existing setup does not of itself exacerbate any differential mode to common mode coupling.

Cecil recall that a current balun/common mode choke is usually constructed by winding some of the differential feedline up on a coil form of some kind. i.e. if not some coax looped up or wound into a solenoind, then a bifilar winding, or a two in hand winding of the differential transmission line into a common mode choke inductance with some level of common mode reactance high enough to add significant common mode impedance in the existing common mode paths.

What difference does the Zo of the current balun make to the common mode reactance of the choke. i.e. to a first order say 8 turns of differential line makes the same common mode inductance wether or not the differential line's Zo is 50 Ohm or 150 Ohm or 300 Ohms or whatever.

Assume there were no common mode problem. How would adding a current balun of either the wrong or the correct Zo cause a common mode problem? And what does the Zo of the line making up the current balun have to do with it's common mode reactance? Not much.

Only the common mode reactance, the CMRR, or the Longitudinal Balance of the current balun, not the differential line Zo of the balun, could cause a common mode problem and those three items have little or nothing to do with the differential impedance Zo.

What am I missing?

Owen:

I picked up the TDR because I wasn't sure exactly where I had a feeder cable failure a couple years ago. Unfortunately, I've been totally unsuccessful at finding an operator's manual for it, so my understanding of how you determine the reflection is based upon guesswork. Perhaps Roy Lewellen will have a chance to look at the photos and tell us which case actually represents the zero reflection case. My (utterly unsubstantiated) assumption was you would be looking for a flat response, on the basis that high or low gives a step response.

If we can agree upon a method of measuring Zo that isn't too burdensome, I'll pick up a couple samples of other types of AC cord at the hardware store and see what it looks like for Zo and loss. The particular samples I've been measuring are from a 500 ft reel of cheap two conductor wire I bought several years ago. I've seen the clear plastic two-conductor cable, sold for speaker wire, at the hardware store, and they, of course, have a wide variety of stuff intended for AC distribution, including 3 conductor and 4 conductor.

Source record: 156438

I was thinking about suggesting that he power the 'scope from one of those inverters powered by a car battery. Then I realized that there would still be capacitance to ground that might allow CM currents at RF frequencies. This might require a Plexiglas work platform suspended high up in the air between tall trees to ensure acceptable isolation... :-) Obviously, an isolation transformer might have no isolation at all at RF frequencies. I guess it would be simple to arrange a power line choke that would eliminate any significant RF making its way down the power line.

Has anyone double-checked to ensure that this isn't all just a simple misunderstanding ? Cecil restated his hypothesis fairly clearly the other day. I thought that I detected a glimmer of sunshine getting through between the two seemingly opposite positions... It seemed that Cecil was stating "A" was true, and everyone else was saying that "B" wasn't true (or was it vice versa?). The words "impedance" and "currents" were getting all mixed-up in the shouting. This sort of question shouldn't require any experimentation in the year 2001. It simply requires careful listening and understanding of the opposite argument and then a single well-aimed shot will deflate the whole thing. It really smells like a misunderstanding.

Best wishes.

Sure. In that case you would have the equal of an isopole,etc. The straight dual 5/8 vertical has about 5.1 dbi gain when properly decoupled. The steep sloping GP version gave about 4.2 dbi or so if I remember right. So the "VD" is slightly better. The problem is, on HF having a dual 5/8 ant is not too easy being you need to insulate the two sections. Just a 10m version would be 21+21=42 ft tall just for the radiator sections. Would be tricky to do in the real world with average materials. But using a single 21 ft 5/8 radiator and 4 steep sloping radials is pretty easy to do. And should have only about 1 db less gain according to modeling. I need to get off my lazy rear and actually build one and see if it works as modeled. I think it will if decoupled properly.. :) MK

288. Eggbeater for 70cm?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-07 00:02:50 UTC
From: Keith Zimmermann <keithk5wx_xspam@qcwa.net>
Message-ID: <3BBF9B38.E2866285@qcwa.net>
Source record: 156441

I've searched the archives here for references to K5OE's Eggbeater Antenna but couldn't find anything.

I'm looking for a simple "starter" antenna that would work OK for some satellite work. The Eggbeater looks interesting. Here's a link to it:

http://members.aol.com/k5oejerry/eggbeater2.htm

I'm just wondering if anyone has any experience with it or has any other ideas that I could consider. I've never been on 70 cm before, so I'm starting from scratch.

Thanks,

Keith, K5WX

Peter O. Brackett wrote:

> What am I missing?
I didn't say what I was trying to say very well so let

me give an example. Let's say I'm designing a choke to work into a 50+j0 ohm load and will build the choke out of 50 ohm coax. Let's say I'll be satisfied with 500 ohms of choking impedance. I choose a toroid and the number of turns to achieve 500 ohms of choking impedance. Now when I operate that balun into a 1000 ohm antenna system, I believe it will cause common-mode problems because the choking impedance isn't high enough.

I've pretty much proved that to myself today. I have a rectified common-mode current detector on my coax. If I tune for minimum common-mode current, I have tuned to the resonant point of my antenna system, at least on 40m where I ran the test. In other words, my common-mode detector is as good as an SWR meter for tuning my antenna system on 40m. The resonant feedpoint impedance is about 36 ohms, the common-mode current is minimum at that point, and rises on each side of resonance. No o'scope problems this time. Just a completely isolated 1N34 diode circuit and a DC voltmeter.

I am attempting to fill out the HomeBrew->Antennas category at
www.hamfinder.com. If you are the webmaster of a page with plans
for an antenna design, or have a favorite that is not currently
listed, please consider submitting it to my directory. The link
for the HomeBrew->Antennas category is
http://www.hamfinder.com/default2.asp?tree=2212

Thanks

Mike (K4NW)

291. Please help a brand new ham...

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-07 00:31:54 UTC
From: Lovely Rita <nanbeek@home.com>
Message-ID: <_nNv7.150884$sM1.41411897@news3.rdc1.on.home.com>
Source record: 156443

Hi there everybody. Well, I've been taking a course to get my ham radio licence and am about to pass the exam in a couple of weeks (I hope!). I don't have much cash (starving student), so I'm starting off small. I was able to buy a 2-meter radio from an acquaintance for a good price, but it's a mobile unit. I want to use it in my apartment. I have a couple of questions and I'm hoping you guys can help me answer them...

I need an antenna. The radio is a Radio Shack HTX-242. The book doesn't really say much about the best antenna to use. What can I buy or make fairly inexpensively? Does it need to be very long? Can it basically be a wire hung out the window? I live on the seventh floor of an apartment building in a fairly quiet city here in Ontario. If I put the antenna out the window, will this be ok to catch the local repeaters? I'm just curious because there's a couple of other apartment buildings around me that are a bit taller and I'm wondering if all the concrete will impede my ability to receive signals.

Anyway, sorry these are kind of basic questions but I'm looking forward to any replies. Thanks in advance!

Nick

Today I built a 1N34 circuit to rectify the common-mode pickup
voltage so it can be used with an isolated DC voltmeter. On 40m,
the common-mode current is minimum at resonance and rises on each
side of resonance. I can tune my antenna system to resonance on
40m by watching the value of the common-mode current. That pretty
much supports my original point. If that holds true across all the HF
bands, I will have a cheap method of automating my tuning procedure.

Gang:
I have sent Will the e-mail address of a ham who has around 200 feet of brand new Belden 75 ohm twin lead. It turned up at the Belton Swapfest this weekend. I am continually entertained by the fact that almost every wanted item I read about on the NG and is described as being unavailable shows up at swapfests, and usually within weeks of the posting. You chaps need to get out and attend more often.

Mike,
Thanks very much. I subscribed to the group and followed up with a search on the antennas you referenced and they invariably showed up on several pages dedicated to the VX-5R. I continued on and found something I think may be even better, though. What about the MFJ Tri-Band FlexiDuck antenna (MFJ-1720S)? They say it's 1/4w unity gain @ 6m | 1/4w 2.15db @ 2m | 5/8w 3.2db @70cm. That matches the best dualbanders and addresses 6m too. It's "a whopping 19 inches" and probably not as flexible as the catwhiskers but doesn't this sound like the most capable?
Let me know what you think.

Hi Cecil,

Now that is indeed an astounding question. I was given to believe by
your own claims that the point of constructing this probe was to
measure Common Mode current. Doubts at this stage of the game?
Peter's noise aside, I've found no unresolvable problems to speak of
until you asked this question (oh, and your lack of one particular
measurement that destroys the logic of your assertion - a tedius point
of mine :-).

Hi OM,

Both you and Peter seem to have a lack of faith in this industry work horse. How many centuries have transformers been built with a faraday shield now? Not much point to an isolation transformer if it doesn't have one.

Any linkage imparted to the big cabinet of the scope to earth, must first find a path to it.

Over and over in this thread I have asked for (and supplied a suggestion for) the complete circuit description (must be a toughie) which would quickly resolve these issues.

Group,

just how much linkage is there between the Common Mode path and the probe path? [hint: I've given one answer for the choking (no one seemed to be able to answer that one either) that is not far off for this as an answer too - if you can draw the diagram].

Perhaps if I supplied it in multiple choice form like the exams.
Naw... I've already done your homework.

Hi Cecil,

That makes absolutely no sense at all unless your antenna pattern is
of no importance to be degraded through a radiating feedline. Your
point seems to be drifting - quickly.

Are you going to approach B&W to add this to their product line? ;-)

"Richard Clark" asked:
> How many centuries have transformers been built
> with a faraday shield now?

But but but... isn't the faraday shield grounded ? A faraday shield may keep the RF off of the power leads, but it will dump it right onto the green ground wire which is exactly where it was heading anyway. At RF, all three power leads (Hot, Neutral, & Gnd) are basically the same (effectively grounded eventually - plus or minus quarter lambdas along the way).

I'm *pretty* sure that an isolation transformer is designed to prevent ground loops and provide isolation at AC power frequencies and is probably pretty good up through audio and beyond.

At RF ? Nah - not without some snap-on ferrite chokes. Obviously this depends on the frequency of the RF. I'm thinking of the HF range when I use "RF".

Equivalent circuit for the usual, 155VAC, painted black, isolation transformer at RF frequencies:
INPUTS >========< OUTPUTS

If I have missed something, feel free to correct me. I always try to keep my confidence level well below my competence. I'm less dangerous that way.

Hi Cecil,

From bad to worse. It is a stretch to blame the choke for failing in doing a poor job it was not designed to do. And what is worse, the choke has nothing to do with balance, the cause of common-mode problems so identified (until this point).

A simple test for blame, would you improve the situation by removing this "cause?"

hey nick
well you can take some 300 ohm twin lead about 60 inch and make a Jpole search the web for that term and they will give you the plans to build it you can find that stuff at radio shack or Kmart you will also need a power supply of around 12 amps or so to get the full 50 watts out the Jpole will work well and you can hang it from almost anywhere and work fine the concrete maybe a problem but not much you can do unless you move

hello,

has anyone put a delta loop up horizontal?

any info i have found has put them up vertical, with the feed point near the ground. i know this is a low impedance feed (under 100 ohms) i am going to feed it with 300 ohm twin lead due to the length i have to run the feed line and because, i just happen to have a considerable amount of it.

i want to put up a full wave loop, but i only have three good supports (trees), not four needed for the loop.

let me know what u think. pls reply email.

thanks

I wouldn't apply the term "degraded" to an antenna system that
has been tuned for minimum common-mode current on the feedline.

I don't blame the choke, Richard. I blame the people who don't

know and/or don't care what impedance the choke is exposed to.
How many times have you read a posting that said, "Put up a
random length dipole and feed it with whatever length of ladder-
line is needed to reach from the dipole to the shack. Hang a
balun on it and you have an all-HF-band antenna."

> And what is worse, the
> choke has nothing to do with balance, ...

According to, "Baluns: What They Do And How They Do It", the
purpose of the choke (current balun) is to force balanced
currents in a balanced transmission line or balanced antenna.

306. Re: Common-Mode Currents VS Loads

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-07 04:26:56 UTC
From: "George, W5YR" <w5yr@att.net>
Message-ID: <3BBFD98E.B850192@att.net>
Source record: 156459

I have three such antennas, Cecil, and all work better than I would expect, especially for my QRP operations.

The three W2DU choke baluns reduce if not eliminate current on the outer braid of the coax from balun into the shack and tuner. The line lengths all reach exactly "from here to there." I experience no "r-f in the shack" problems despite lack of an "r-f station ground." Even when operating QRO at 100 watts, I am unaware of any r-f problems attributable to common-mode currents, although I use a fair amount of "outboard" audio gear on SSB and use computers in the shack for the digital modes. I have band coverage from 80 through 10 meters. My transmitters always see 50-ohm resistive loads. With my two 20-meter EDZ antennas at right angles, I can switch pattern 90 deg with the flip of a switch.

What's wrong with this picture? Or, maybe it is just luck . . . ?

Source record: 156460

I operated a triangular horizontal full-wave 40-meter loop for some time on 40 through 10 meters. Fed with ladderline, a W2DU balun and coax to the tuner. I recently reoriented the antenna to open it up into more of a trapezoid in order to gain more included area. The antenna height above ground ranges from about 20 feet at the lowest to about 35 feet at one end/corner.

I would not be concerned about the lack of the fourth support. Put up the three-support version with as "open" a loop as you can, and enjoy operating. I predict that it will work better than you might expect. If later you can add more supports and open things up a bit - always aiming for that "perfect" circle configuration - then so much the better.

This antenna has proved to be a real winner on 40 meters for close-in stations that were difficult copy on any of the horizontal dipoles or the vertical. There are times when DX stations on 20 are louder on the loop than on any other antenna.

All in all, I have found the 40-meter horizontal loop to be an indispensable antenna.

Source record: 156461

Jack has done some excellent work. I'd like to point out just a couple of things to watch out for when making transmission line measurements.

One is the effect of loss. If you use the full equations for calculating transmission line characteristics in the presence of loss, you'll find that surprisingly small amounts of loss will skew the measurements considerably. This is particularly true when you're making measurements with lines terminated with impedances far from the line's characteristic impedance. When doing TDR measurements with a step generator, you'll see the baseline rising with time. This is a consequence of loss -- if the cable is extremely lossy, the step will eventually rise to its open-circuit value. This is the reason I prefer the trimpot method.

I'll illustrate the second thing to watch out for with a story. I've told it at least a couple of times before on the newsgroup, but it looks like a good time to tell it again. Just skip it if you've heard it before. When teaching a class on TDR, I found a great way to get the students' attention. I had a piece of ribbon cable, just two conductors, a few inches long, with one end soldered into the center of an SMA connector and the other to the shield, and open circuited at the end. Connected to a high speed TDR, the reflection from the end of the cable was obvious, but there was another, smaller reflection from roughly 4/5 of the way to the end. I pointed out that ribbon cable isn't constructed with controlled impedance in mind, so there must be a wow in the cable. So I ran my finger along the wire until the reflection from the effect of my finger was at the same point as the reflection from the presumed cable defect. Then I took out some cutters and cut the line an inch or so shorter than where the reflection was coming from. The result? A reflection from about 4/5 of the way to the new end. At that point I had their attention. What was happening is that a common mode wave was also launched along the cable, but because its field was primarily in air, it hit the end and returned sooner than the main differential wave reflection. Putting a ferrite core or two over the two conductor line (making a W2DU-style current balun) reduced the common mode reflection to a very small value. This effect isn't restricted to the time domain even though it's more obvious there. The cautionary note is that it's tricky to make good measurements of a twinlead line using conventional single-ended equipment, and some effort has to be made to suppress the common mode response. Again, the TDR trimpot method insures measuring only the differential impedance.

Consider the term isolation. It means to separate the two sides. A
ground interdiction to capacitively coupled currents is exceedingly
effective. Any problems that the introduction of this shield to the
system adds is a product of poor initial design, not the addition of
this component.

You speak of the mains in the hushed tones of being in the presence of
ground. These are just lower ohmic loss antennas, poorly erected for
sure, but active at RF just as any other wire would be if driven by a
Common Mode source. In fact this is such a certainty that the power
folks put a shield between you and them at the pole's transformer
(nothing personal mind you). And yes, the coupling will dump some of
the load to ground - if you have 1/10th wave ground leads from every
electrical connection direct to earth (barely true at 160M for some
folks).

These are the "common" AND classic sources of Common Mode problems.
All should note that the mains arrives in a balanced configuration too
and is often the first victim to Common Mode and the mysteries of its
solution.

Hi OM,

As you put it, the prevention of ground loops is found in the isolation of one system's return path from commingling currents with another system's return path (AKA "Ground Busting"). The input circuit, the shield, and the output circuit can all tie to the same ground and remain isolated, but not through the same conductor. Each element may also go to separate "local" grounds. This is reductio ad absurdum however as the shield should not find its own way, but rather tie to the input or the output. Sometimes you drive the shield with the output and achieve considerable depth of isolation (you are never really alone).

Ground in this sense is not the cliche of 0 Ohms. It is in the sense of mother earth and the infinite reserve of replacement current available on demand. The sheet form of grounding does this very effectively where a rat's nest of ground leads runs a distant second, and the daisy chain a poor showing.

I will recite from a reference to give you some perspective:
"Grounding and Shielding Techniques in Instrumentation," Ralph Emerson.
"By carefully following proper techniques, effective inter winding capacitances less than 0.05 pF and leakage resistances greater than 10,000 MOhms can be guaranteed. Actually values less than 0.001 pF and greater than 100,000 MOhms can often be obtained..."

All the high speed TDRs (such as the Tek CSA and TDS 800 series and the older 7000 series plugin units using S- type sampling heads) use a step rather than a narrow pulse. You lose a lot of information by using a narrow pulse instead of a step. As far as I know, narrow pulses are used only on TDRs designed for making measurements on long cables, like the Tek 1500 series. These TDRs have to put out a large pulse so the return can be seen in the presence of a lot of loss, so making a step would require too much energy.

The high speed TDRs I'm familiar with put out an essentially square wave with fundamental frequencies in the hundred kHz to few MHz range. This allows the step to stay high plenty long for the types of measurements being made with these TDRs.

So, am I to answer this as your mistake, or your mistake of
attribution, or your mistake of misreporting, or their mistake of
analysis, or the editor's mistake for inclusion... there are so many
things that can go wrong in arguing your thesis through a third party.

You've omitted the simple test for the choke being a contributor to
the problem as you've put it. So. If I remove the choke, does it
improve the situation?

I am about to put up a 1/4 wave HF trapped vertical (DX88)
antenna in my back yard. Could anyone share his advice
on how to setup a ground radial system on a fairly steep
(45+ degree) slope?

I had in mind burying in the ground about 30-40, twenty feet long
radials, but since the terrain is sloping I am not sure how to
correctly go about it. Should the radials be the same lenght in all
directions, or perhaps I should make 'em shorter "up slope" "down
slope." Does it matter?

Any suggestions would be greatly appreciated.

315. Folded dipole/Inverted-V choices & confusing calculations. . .

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-07 08:01:26 UTC
From: Will White <googlyelmo@earthlink.net>
Message-ID: <3BC00BB2.2F5D951E@earthlink.net>
Source record: 156468

I finally am in a QTH without any landlord or neighbor-imposed restrictions on antennas. I have about 70' of horizontal space, and can get the apex of my wire(s) up 45' [ends no more than 25'], so I have decided on an inverted-V/parallel-"fan" configuration for 40-10 meters.

What I really have to decide is whether to use 300-ohm twin-lead folded dipoles fed with a single line of the same, or single wires fed with one lengthRG-59 (or 75-ohm twin-lead, if I can find it). I would like to put up the folded dipole, as I see some advantages in matching, SWR bandwidth, and radiation efficiency, but I have some concern about mechanical matters, namely constructing a solid, durable center connector. How can I join *one* twin-lead feeder to *three* twin-lead folded dipoles, and how can I secure the ends? Standard egg and dogbone insulators won't fit the bill, and those "ladder-grabber" thingey's will accomodate neither TV-twinlead, nor multiple wires, in the center. Suggestions and guidance on how to fabricate these?

Further, as to measurements, I understand that both inverted-V's and folded dipoles are resonant at somewhat less than the conventional 468/f[MHz] formula. From Joe Carr's "Practical Antenna Handbook" I have the formula for inverted-Vs as 440/f[MHz]. According to my 16th edition (1991) ARRL Antenna book , I am told to short the two conductors of a folded dipole in from its ends, this point determined by computing 492*velocity factor/f[MHz]. Thus, I am left in a sort of arithmetical morass, needing as I do to juggle these calculations. I have to account for the shortening effect of the inverted-V, and balance that figure with the *shorting* point on a two conductor folded dipole. How do I calculate a length that while not perfect or exact, puts me close to resonance, within a minor trim or two? Oh, and what to do, what to do, to take into account the fan or parallel arrangement I have planned? Having three antennas fanning out in parallel *must* affect impedence and resonant frequency, but how? Please, any aid with incorporating these three design formulae will be a great help. I hope I have stated my problem clearly and with a minimum of babble. Help, help, and thank you!

Will White
KD7BFX

P.S. Why not simply cut off the ends of a folded dipole and solder together @ the 492*VF/f point? Why leave the part of the twinlead that is 'outboard' of the shorting point attached at all?

No one seriously trying to measure common mode would use a scope, let
alone one connected to a unshielded and unisolated "current"
transformer.

With a small resistor floating at the end of a hunk of coax with or
without a balun the common-mode current at HF would be basically nil.

Hi Mike ,
Check out the following articles by LB Cebik about Horizontal Loops. Think you'll find it dispells some myths about the critter. I used a 160m horizontal loop for many years and it worked like gang busters up through 10 m , unfortunately I lost 2 trees in the 1989 Ice storm and don't have the possibility of getting it back up until they grow back , hi hi.
73 and good luck, Dave Kc1di

See my latest postings, Tom. I got the same results by

rectifying the voltage from the common-mode pickup coil.
The common-mode current is minimum at the resonant point
in my antenna system and rises on each side of resonance.

=====================================

Jack, the 105-200 MHz graph is quite informative. Much meticulous effort has been involved. Thanks very much !

The idea behind doing a Zo vs freq over several wavelengths of line is that the value of the termination is immaterial. Its sole purpose is to reduce the swings in line input impedance above and below Zo to something the bridge can easily manage and to values which can be conveniently plotted.

For the purpose of determining Zo it doesn't matter even if the value of the termination changes with frequency. (It does matter when determining velocity)

Of course, if the line is long enough and attenuation high enough the ripple superimposed on measured input impedance will be small enough without a termination.

The sloping regression line does not mean very much except that its slope is an indication of measuring error. A straight horizontal line through the geometric mean of the peaks and troughs is what's needed. The theoretical expectation is an almost perfect sinewave superimposed on a horizontal line with sinewave amplitude reducing

exponentially with increasing frequency.

True Zo on all real lines continues to fall with frequency for the same reason as velocity (previously explained) continues to increase. But above 5 or 10 MHz the residual downward trend is entirely lost in line and measuring imperfections.

From the graph it is obvious from the amplitude of the swings about the mean that the *100-ohm termination is very much different from line Zo.* If the measuring bridge and setup is to be believed, line Zo between 100 and 200 MHz is approximately 125 ohms. Furthermore, this implies that Zo is also 125 ohms at much lower frequencies. Is there another discrepancy somewhere ?

From my own rough measurements some years back at low HF on Archer speaker zip-cord I prefer the higher 125 ohms value. My own measurements (Autek) on much longer lengths (120 feet and hence more accurate) were a little higher around 130-135 ohms. But samples vary considerably between manufacturers.

The uncertain meanders of the graph vs frequency and the difficulty in judging where to draw the horizontal line is an indication of the sum of the uncertainties in the whole measuring setup. That's why the method is amongst the best.

If I had to prepare a measurements laboratory certificate on the measurements discussed in this thread I would state the 2-sigma uncertainty limits as being +/-15 percent. Which is about the same as sensible manufacturing tolerances.

Regards, Reg, G4FGQ

I own one of the earliest AT4K units. The fan runs off of the 12 volt wall wart. It does not move a great deal of air. It is not like the blower on my QRO DX-2500HF. I think it is there mostly for bragging rights.

Anyway, on 160, I run legal limit SSB all over the band on an antenna that is cut for the bottom of the band. I am matching SWRs of up to 3 to 1. Nothing gets hot, nothing arcs, nor must the fan go on. Maybe if I was running 1500 watts of RTTY I would need a fan. I don't know.

I bought the AT4K after I saw the prototype at Dayton. I don't think the internals of the present unit are any different, but the padding capacitor switch seems to not be there any more. I don't know if that means that values for any of the variable caps have changed. I have never had to use the padding capacitor.

I have tried the unit with loads up to 2300 watts or so, but if it is into a dummy load, who cares, as a dummy load should be close to 1 to 1 swr. I have never seen a 5 to 1 swr dummy load. Therefore, what a tuner will handle into a dummy load means very little. Under real world conditions, the AT4K does a great job, fan or no fan.

Maybe I should avoid cars with air bags. That may mean bad brakes.

Hmmm...

You're in North America (KB7...), so we have the same power system.

Yes, the mains "arrives in a balanced configuration" (230VAC), but they also arrive with a grounded centre tap (Neutral, grounded at the pole, grounded again in your panel). Most household appliances (including 'scopes) are connected between one Hot and the Neutral (115VAC) and are, from the beginning, "unbalanced". The fact that the 230VAC power "arrives....balanced" might be applicable only to ovens, clothes dryers, baseboard heaters and hot water tanks.

But I don't think that this has anything to do with my possible misunderstanding (?) of how an isolation transformer is built and how well it would isolate a scope at RF frequencies (HF bands).

I fear that we might be communicating orthogonally ('talking' past each other - so to 'speak'). Trust me that I don't think for one second that you don't understand your theory. I just want to track down the root of my possible misunderstanding in case I learn something along the way.

It's important to note that I'm referring to HF frequencies where the outlet grounds can't be trusted. Household Grounds (at the outlets), the Hots and the Neutrals are all well inter-connected (at RF) by the capacitance of the many miles of wiring in the average house and the odd refrigerator along the way. The quality of the "RF ground" at any particular outlet depends on the length of the wiring to that outlet (leading to the good RF ground - usually outside) as compares to the wavelength. Other than the inconvenience of the dangerous AC voltage, the Hot (black wire) would probably be about (note: about) as good an RF ground as the official Ground (green) at RF (HF).

Allow me to reiterate my position. Let's assume a 'scope is reasonably well connected to ground by way of the power cord. Can that 'scope be isolated from ground ("floated") at RF frequencies (HF) by use of a standard isolation transformer with a normal faraday shield between the windings ?

I say "Not reliably".

I've seen faraday shields in plenty of transformers; the faraday shield is the copper foil between the input and output windings. Isn't that copper foil usually attached to the green wire which leads down to the three prong plug and the outlet ground ? Although the effective "inter-winding capacitance" may be virtually zero, the capacitance between the 'scope side winding of the isolation transformer and the faraday shield is obviously huge at RF.

Then the green ground wire is obviously not much different than the Hot or the Neutral so far as RF is concerned. It is similar to a transistor audio circuits where the +Vcc is heavily bypassed to ground and may be (and is) treated as signal ground. The Hot and Neutral in your household wiring are heavily bypassed to ground through all sorts of paths; probably long before any of them reach a good RF ground.

If you're trying to float a 'scope at RF, I'm thinking that you might get better RF isolation (for a 'scope) at a particular RF frequency by using a different length of extension cord to make a quarter lambda to the "good" RF ground, than by trusting an "isolation transformer". Even better, some ferrite snap-on chokes might do it.

I don't understand how it could be reliably accomplished with some copper foil connected to a green wire given typical household wiring.

What am I missing ? Hopefully I've been clear enough that you can find the root of my misunderstanding (if any) and skewer it with an quick and easy rebuttal. I don't want to consume your entire holiday weekend !

Thanks for taking the time.

I would "bury" the radial wires only as deep as needed to keep them out of the way. There is no electrical benefit to buried radials - the deeper they are, the worse they work, in general. You are trying to collect ground return current through the radials and not through the soil, so placing soil around the radials is counterproductive.

Depending upon frequency, the depth of penetration of ground currents can be up to several feet. Burial of a few inches or even an inch or less has few electrical consequences but is for physical security and convenience.

Since "buried" radials are not electrically resonant, their length is a moot point. Make them as long as circumstances permit, although tests have shown that radial lengths much in excess of 0.2 wavelengths are not that more effective. The notion is to create a field of copper under and radially around the antenna - the more the better.

Will:
You are going to be fighting a losing battle with the approaches you describe. Commercial twin lead was never designed to survive the mechanical requirements that an end supported free span of more than 5 or 10 feet requires. Consider that long term survivable dipoles require either Copperweld or large hard drawn copper conductors. The small diameter stranded conductors of twinlead are made to be supported by stand-off insulators every 3 to 5 feet in a typical installation, and are simply not robust enough to stand up in the configuration needed. The transmitting twin-lead will last the longest, of course, but even that will require some special mechanical treatment on the ends to keep brittle fracture from occurring.

As far as length is concerned, ground proximity and characteristics have the most effect on resonant frequency and impedance. You could embark on an ambitious measurement campaign of the environment, or do what most people do when faced with your requirements, put up something you know is too long, measure it, and iterate to the desired resonance. The books never say this, because it puts off to many people who envision it as too much trouble. The multiple dipoles in parallel tend to lower the resonant frequency of each other, so cut a set to the book length, measure the frequency, and shorten them to fit.

I would think the proper approach is to complain to your service provider
about inadequate coverage.

Because, consider the following numbers:

Most commercial yagis of reasonable size in this frequency range are spec'ed
at 8 to 9 dB.

A really, really good yagi might provide 10 - 12 dB of gain.

100 feet of RG-58 at 900 MHz has about 20 dB of loss, so if you run 50 feet
of it, you only break even. Expect to be buying Heliax (Andrew Corp) and a
good commercial (Celwave, Allen Telecom, Antennex, etc.) antenna if you
expect to gain any significant performance advantage.

I have an FT-114-61 toroid with 20 turns on it that I use for sensing common mode currents. It is just large enough to slip over an S0-239 barrel. Its output is in volts across a 110k resistor which is then rectified by a 1N34 diode circuit. The following chart contains the DC voltage output which can roughly be converted to mA by multiplying by 13. The antenna system is resonant at 7.15MHz and the power input to the tuner is 9 watts. PU is the pickup toroid and measurements were made with and without the balun.

XMTR---tuner---PU---1:1 current balun---450 ohm ladder-line---dipole
with and without SWR~12:1

Frequency Voltage without balun Voltage with balun

7.00 3.2 2.3
7.05 2.8 1.7
7.10 2.4 1.2 Capacitive
7.15 2.1 1.0 Resonant
7.20 2.8 1.1 Inductive
7.25 4.1 1.4

With or without the balun, the differential impedance is affecting

the value of the common-mode current. At resonance, the balun is decreasing the common mode current by a factor of 2 and in both cases, common mode current is minimum at system resonance. SWR on the ladder-line is about 12:1.

One interesting effect is that capacitive loads tend to give the inductive balun more trouble than do inductive loads.

You've argued the imbalance well - hence my warning of this being the
"common" source of Common Mode problems.

>
snip
>
>
>Allow me to reiterate my position. Let's assume a 'scope is reasonably well
>connected to ground by way of the power cord.

This is entirely the point, there is no assurance of the 'scope being
reasonably well connected to ground by way of the power cord. Most
pro's snip the ground pin off the connector first thing and establish
their own ground.

For the 'scope, ground is wholly unnecessary, it has a cabinet for
shielding, not grounding. It is the responsibility of the user to
provide ground if the user has any expectation of making a useful
measurement.

>Can that 'scope be isolated
>from ground ("floated") at RF frequencies (HF) by use of a standard
>isolation transformer with a normal faraday shield between the windings ?

Ah! You have an expectation of the isolation transformer that is not
supported by standard usage. This was my earlier admonition in that
you have not taken the term "isolation" in its proper context. This
device is a coupling mechanism with an input circuit and an output
circuit. We are isolating the circuits only. That is, the ground
systems are completely independent of each other - they are isolated.
This says nothing of either circuit being isolated from ground (much

less which ground).

The accomplishment in this class of device is in the side-by-side existence of these two circuits with massive, conducting surface areas separated by at most a millimeter, and yet their capacitive coupling is so small that no one here could measure it.

That either circuit has this massive swamping capacitance to ground is another matter. And it is an extremely inconsequential matter. If we remove the faraday shield, the opposite circuit, now fully, capacitively coupled presents an identical swamping. Hence there is no additional burden brought to the configuration through the addition of the shield. That is to say, if we were worried about this being a Common Mode current path for RF currents to ground, it was always such a path immaterial of the inclusion of the shield.

If we were then to stipulate that the shield does not matter to the context of the problem: to wit that this is by definition (either way) a low Z path direct to ground (and the best ground the technician can find!). Exactimundo.

BUT a short circuit to ground from the cold end of a Hi Z probe is of no consequence to the field being probed. The complete path is still Hi Z (yet again, barring complications of wavelength in regard to physical length and external Common Mode coupling), IF Cecil had made a connection of the scope probe ground clip to the exterior ground shield of the system equipment, THEN all bets are off. Otherwise, this potential Common Mode path Z is dominated by the Xc of the ground clip capacitive coupling to that same system equipment. I trust Cecil adequately "isolated" this coupling through distance.

Hi OM,

Floating a scope is another invitation to be amazed. It costs to be sure, and could cost big time, but in principle I already answered that one (perhaps too elliptically).

Retaining the earlier nomenclature, if you take the output and use it to drive the shield, the shield's potential becomes the same as the output and hence with no potential difference there is no current. ANY Ground path behind that shield disappears from the view of the output lead. If the coupling between input and output is 1:1, then the input loses sight of ground too. And if I could prostitute Kirchoff, if there is no current out to that circuit, there is no current in from that circuit - isolation.

This is a purist's circuit, cost be damned; because there is the power lost to driving the shield to hide ground. In other words, I skipped over the hard stuff of actually driving that complex load. Or in even more other words, a technical shell game. If your goal is the absolute best effort to snub CM paths, then open your wallet.

This previous discussion may take a heavy toll, faith-wise, but I have used these techniques on the bench to measure capacitance out to the 0.001 pF value mentioned in my reference. This bench is located in the land of precision sources, three lead capacitors and four lead resistors.

Let me point out that my fantasy bench already has its correlative in Cecil's differential scope plug-in (a three lead input). It also suffers the complexity of my example of the driven shield, but by driving a "ground" lead instead (and maybe some internal shielding).

Now when I say it suffers the complexity, I am being literal. If there is a common mode problem anywhere it is everywhere. This plug-in has to withstand the Common Mode stress that it is measuring. One common requirement was that the Common Mode potential cannot exceed the rail voltage of the input devices. This is the hidden killer of applying this plug-in because if the operator is a novice, he may not appreciate that his connections are to a potential that presents unpredictable responses. This can lead to latching of the input and a curious 0 or constant offset reading. The skilled operator usually picks up on this quickly.

MY SYSTEM ALSO IMMEDIATELY SUPERIMPOSED A VIRUS MESSAGE ON THE
SCREEN WHEN I OPENED THE "URINATE" SUBJECT.

The message said the name of virus is "alt.config" and it is
somewhere on the hard drive. I seached for it on the hard drive.
Nothing found.

I searched for the text "I need to urinate". It was in two
temporary large memories associated with this and one other
radio-related newsgroup. I deleted both temporary files..

The machine now appears to be behaving normally.

What is the virus alt.config supposed to do ?

Reg, the "virus" turned out to be merely the false JAVA message on your screen that your computer was infected. I immediately ran a full Norton Anti-Virus check on all hard drives and nothing was found, nor did NAV flag the incoming posting. I was unable to find "alt.config" anywhere on the computer.

As I posted earlier, any of us who were dumb enough to read a posting with that subject line deserved to be fooled! <:}

Source record: 156400

Reg:

Thanks for analysis. I've today also look at the same line section with my HP 8754A network analyzer over a range of 4 ... 200 MHz.

I've posted the CRT shots at http://home.cox.rr.com/k8zoa/Swept_Frequency.htm

If you look at the shot for 100 ohm termination, its shape tracks the discrete |Z| measurements that I made yesterday, including the marked peak-peak differences between the peak-trough around 125-140 MHz vice the 185 MHz - 198 MHz pair.

Consequently, I think this is "real" and not an artifact of the measurement instrumentation.

Note also that I was able to get a reasonable return loss flat response from 4 - 50 MHz or so with a 108 ohm termination, but that did not cause a flat response above this frequency. In the 100 - 200 MHz range, not even 130 ohms produced a match.

It looks to me as if the Zo on this type of line must shift significantly as frequency increases.

Or am I not reading the data correctly?

Jack K8ZOA

"George, W5YR" asked:
> Happy to see it, but wonder who you had in mind? <:}

Sorry, doesn't your newsreading system keep the posts organized into threads
?

Mine is MS Outlook Express.

I supposed I could simply repost the entire ever-growing thread, but then it would take 6 years of scrolling down to find the latest addition at the very very bottom, except some people add their latest at the top, and then others add at the bottom again and the line of >>>>>>>>>>>>>>>>>>>> ends up wrapping around. What a system... :-)

I agree that perhaps I overly snipped that last one - sorry. It was to Richard's latest dissertation on isolating 'scopes. In the end, it appears that he and I have no points of disagreement (so far as I can see).

On Sat, 06 Oct 2001 22:03:24 -0700, Roy Lewallen <w7el@eznec.com> wrote:

|Jack has done some excellent work.

Indeed!

|One is the effect of loss. If you use the full equations for calculating
|transmission line characteristics in the presence of loss, you'll find
|that surprisingly small amounts of loss will skew the measurements
|considerably. This is particularly true when you're making measurements
|with lines terminated with impedances far from the line's characteristic
|impedance. When doing TDR measurements with a step generator, you'll see
|the baseline rising with time. This is a consequence of loss -- if the
|cable is extremely lossy, the step will eventually rise to its
|open-circuit value. This is the reason I prefer the trimpot method.
|
|I'll illustrate the second thing to watch out for with a story. I've
|told it at least a couple of times before on the newsgroup, but it looks
|like a good time to tell it again. Just skip it if you've heard it
|before. When teaching a class on TDR, I found a great way to get the
|students' attention. I had a piece of ribbon cable, just two conductors,
|a few inches long, with one end soldered into the center of an SMA
|connector and the other to the shield, and open circuited at the end.
|Connected to a high speed TDR, the reflection from the end of the cable
|was obvious, but there was another, smaller reflection from roughly 4/5
|of the way to the end. I pointed out that ribbon cable isn't constructed
|with controlled impedance in mind, so there must be a wow in the cable.
|So I ran my finger along the wire until the reflection from the effect
|of my finger was at the same point as the reflection from the presumed
|cable defect. Then I took out some cutters and cut the line an inch or
|so shorter than where the reflection was coming from. The result? A
|reflection from about 4/5 of the way to the new end. At that point I had
|their attention. What was happening is that a common mode wave was also
|launched along the cable, but because its field was primarily in air, it
|hit the end and returned sooner than the main differential wave
|reflection. Putting a ferrite core or two over the two conductor line
|(making a W2DU-style current balun) reduced the common mode reflection
|to a very small value. This effect isn't restricted to the time domain
|even though it's more obvious there. The cautionary note is that it's
|tricky to make good measurements of a twinlead line using conventional
|single-ended equipment, and some effort has to be made to suppress the
|common mode response. Again, the TDR trimpot method insures measuring
|only the differential impedance.

This discussion has prompted me to post a revision to my 'ladder line page" that I wrote some time ago but never got around to putting on my home page at:

http://users.triconet.org/wesandlinda/

Included in this revision is a link to a copy of a paper that might be of interest to this discussion.

Follow the link to ladder line and then look for the link to "Characterization of Balanced Transmission Line by Microwave Technique."

Threaded or not, posts don't show up on different news servers in the same

Hi Richard,

Thanks for answering my message so quickly. Because now it's late I
want to say to you that thanks for willing to send me a lot of your
files of the Sierpinski gasket of your website so that I can continue
with my thesis and start with very important simulations.

A question: Is it possible to use the package Eznec which you used for
wire antennas also to approximate patch antennas. What I have to do is
namely simulate a Sierpinski gasket patch!! antenna from the IEEE
paper "Multiband Sierpinski patch antenna of C. Borja". Is it possible
to change your designs for my simulations to approximate this patch

antenna by using the wire method that used Eznec??

Thanks for supporting me and I will wait till you send me your files.

Rafael

P.S.Send them to one of my mail addresses:
rafahol@hotmail.com (max.1 MB)or better to R.Hollander@its.tudelft or
r.hollander3@chello.nl

When I tried to model mine on one of the computer programs, it showed the radiation pattern pattern was vertical. So I rotated my 40 loop into the vertical position but changed the shape to a delta loop. I don't know what difference it makes but the noise is greatly reduced.

But I am no expert on computer modelling... so my results could be completely wrong.

This antenna you can build yourself for a few dollars.
you can feed it with 50 ohm coax.

http://www.cebik.com has lot of info on many antenna types.

Source record: 156408

One further data point.

I found an interesting zip-cord Zo measurement by Jerry Hall, then technical editor of QST, in "Zip-Cord Antennas -- Do they really work" QST, March 1979, pp 31-32.

The zip cord he measured matches the description of the sample I have, except his had brown insulation whilst mine is black.

His measured Zo is nominally 105 ohms, with the following spot values:

10 MHz: 107 ohms
15 MHz: 105 ohms
29 MHz: "slightly lower"

Apparently he had problems measuring at 29 MHz due to line radiation.

This gives me confidence that the one or two values I've seen around 115 ohms are an aberration and that the 100 - 108 ohm measurements are correct.

Hall did find significantly lower loss than I measured, however. I'm going to revisit the attenuation. Wes Stewart's paper gave me a clue as to why I may be seeing excess loss (actually radiation, not loss), so I'll see what I can do to prevent or at least reduce radiation. It's also possible that the blackening agent used in my sample has greater RF loss. Normally the dielectric loss in cable is not the dominant factor, but this may be a special case.

The increase in apparent Zo at frequencies > 50 MHz could well be due to line radiation in large part. It wouldn't take much imbalance to radiate significantly.

> improve the situation?
Using 20T on an FT-114-61 toroid for the common-mode PU pickup,

and rectifying the output with a 1N34 circuit, here are the
results. Multiplying the voltage by 13 gives the approximate
current in mA. Power input to the tuner was 9w. SWR on the
ladder-line was about 12:1. Antenna system resonant at
7.15MHz with about 36 ohms at the balun.

XMTR---tuner---PU---balun---450 ohm ladder-line---dipole

Frequency No Balun #61 Toroidal Balun #77 W2DU Balun
7.00 3.2 vdc 2.3 vdc 1.00 vdc
7.05 2.8 vdc 1.7 vdc 0.93 vdc
7.10 2.4 vdc 1.2 vdc 0.65 vdc
7.15 2.1 vdc 1.0 vdc 0.55 vdc
7.20 2.8 vdc 1.1 vdc 0.59 vdc
7.25 4.1 vdc 1.4 vdc 0.87 vdc

With or without a balun, minimum common-mode current was achieved
at resonance, i.e. at minimum differential impedance.

I'm sure the noise was reduced unless it was coming from the sky.
You'll have to do better than that to have a decent
antenna..."completely wrong" may be operative.

CAM, W5DXP wrote:
"With or without a balun, minimum common-mode current was achieved at resonance, i.e. at minimum differential impedance."

As differential load voltage is a function of the load impedance, and this voltage is the main source of common-mode energy, Cecil`s dip in common-mode at resonance seems reasonable to me.

I don`t see a serious balance problem caused when two similar scope inputs accommodate a differential signal. Similarity of the two inputs should ensure pretty good balance to ground, if balance of the cable and its input are maintained.

Best regards, Richard Harrison, KB5WZI

359. List of the rec.radio newsgroups

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-08 05:29:19 UTC
From: jeffreyh@Hawaii.Edu
Message-ID: <9prdjf$c0c$1@news.hawaii.edu>
Source record: 156411
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.boatanchors

```
Archive-name: radio/personal-brief-introduction

In an effort help ensure a poster's article reaches the appropriate
audience, below is a list of the rec.radio newsgroups. In most cases,
a group's name will explain its purpose. Cross-posting should rarely
be necessary.

rec.radio.broadcasting (devoted to the broadcast industry; moderated)
rec.radio.cb
rec.radio.info (periodic informational bulletins; moderated)
rec.radio.scanner
rec.radio.shortwave
rec.radio.swap (for buying, selling, and trading; not a discussion group)

rec.radio.amateur.antenna
rec.radio.amateur.boatanchors (tube-type communications equipment)
rec.radio.amateur.digital.misc (packet, pactor and other digital modes)
rec.radio.amateur.dx (long-distance amateur communications)
rec.radio.amateur.equipment (questions, comments regarding commercially-
built amateur gear; not for buying/selling)
rec.radio.amateur.homebrew (devoted to home-building ham gear)
rec.radio.amateur.policy (issues include code, restructuring, local
restrictions in conflict with FCC R&R)
rec.radio.amateur.space (satellites, meteor scatter, EME)
rec.radio.amateur.misc (any amateur topic not covered in the above groups)

(At least two other English language radio hierarchies exist, prefaced
with "uk" (United Kingdom), and "aus" (Australia), in place of "rec.")

Again, cross-posting should rarely be necessary. Many times, a long-
running thread results from a single cross-posted article, and its
content drifts further and further away from being "on-topic" in the
various NGs which receive each and every followup.

For more detailed information, see "Guide to the Rec.radio Newsgroups"
posted on the 15th of each month.

360. Re: 75-Ohm twin-lead: still available?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-08 08:50:18 UTC
From: Dan AC6LA <ac6la@arrl.net>
Message-ID: <eNdw7.20037$ev2.28393@www.newsranger.com>
Source record: 156413

Reg Edwards says...
>True Zo on all real lines continues to fall with frequency for the
>same reason as velocity (previously explained) continues to
>increase.

Reg,
This leads to another question. Jack's measurements on zip cord and mine on RG-58 confirm both parts of the above statement, although there seems to be some difference of opinion as to measurement inaccuracies versus the frequency at which the above phenomena "flatten out". But my question now is, does the relation
Zo = 1016.703 / (CpF * VF)
hold at lower frequencies where both Zo and VF are changing with frequency?

You've stated (and other references confirm) that the capacitance per unit length (per foot in this case) stays fairly constant across a broad frequency range. The 1016.703 in the above equation is a physical constant, leaving just Zo and VF. With inexpensive test equipment (ie, an antenna analyzer) I can determine the frequency of input Z peaks on a shorted-load line (at odd multiples of 1/4 wavelength) to within a few KHz, meaning that I can get an accurate value for VF at several different frequencies. So if the above equation is not a "high frequency approximation" could I not use it to determine Zo with the same accuracy as VF?

73,
Dan AC6LA

361. Bilal Isotron 80

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-08 12:17:47 UTC
From: kg4fet@aol.combadspam
Message-ID: <20011008081747.00187.00002394@mb-fp.aol.com>
Source record: 156414

I need a bit of help with one of these and since the support is done by phone only and a long distance call at that I would guess that should tell me something about the company itself. I could not find an email address except to order a catalog and I have on of those. Lets get to the meat of the question. I bought an Isotron 80 at the Poormans Hamfest yesterday and it seems to be very different from the recent pictures of and of the 80 mtr version that I have seen. This one is a bit wider according to the specs printed on the limited "homepage" of the Bilal Isotron. It has 2 wings on it that I have never seen before that terminate in a 1 7/8" square piece of aluminum. This would lead me to believe that it is and older version. These wings are made of the same 1/4" aluminum rod that the "load" is attached to. They measure 2" to the bend and 10 3/4" long. The "published" width of the Dummy load er ah 80 mtr Isotron is 16 inches and mine is 17 inches. Although this antenna is supposed to tune at any elevation I cannot get it to tune at all. The question is am I missing some parts, or am I missing something else? I am wondering is there is anyone with an Isotron 80 of similar configuration that might still have their directions or the paper work that came with their antenna that they would not mind passing on to me. I bought this with a specific need for a comparison antenna for some experimental antennas I am working on for 80 mtrs. I know what I bought is basically a dummy load, and its a good thing I didn't pay more then 3.00 for it but I would like to get it to work. I have pictures of the antenna so if you need them to help ID the antenna please let me know and I will send them along.
Thanks for the Bandwidth and the time you took to read my ramblings.
73 and thanks to any and all who can help in advance
DE KG4FET Sandor Friday mornings net control for the Early Bird Transcontinental net. See ya (well hear ya) there!!!!!

L.E. Cebik had an article in the August 2001 issue of QST about circular polarized Moxon rectangle antennas for 2 meters and 70 cm. They look like a possible alternative to the Eggbeater.

364. More ??? on Roberts Dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-08 14:19:47 UTC
From: AC6V <ac6v@amsat.org>
Message-ID: <3BC1B603.2D544A89@amsat.org>
Source record: 156417

The ARRL Compendium Vol 2, page 19 describes an inverted bobtail --
THE ROBERT'S TAIL ANTENNA. Don't think this is the one asked about.

At URL: http://www.narte.org/nn183/weston.html
there is reference to a "Roberts Dipole" which is used in test
measurements. Does this jog anyone's memory ???

Also at URL
http://www.amta.org/AMTA2001/Schedule/abstracts/A01_042.pdf
there is info on feeding a Roberts Dipole.

Anyone use this antenna in a test environment ???

366. Re: 75-Ohm twin-lead: still available?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-08 14:43:55 UTC
From: Jack Smith <jsmith@mnsinc.com>
Message-ID: <gke3st06rd4np6v4e07harsg7u8ggjp1h3@4ax.com>
Source record: 156269

I earlier said
>
>Hall did find significantly lower loss than I measured, however. I'm
>going to revisit the attenuation. Wes Stewart's paper gave me a clue
>as to why I may be seeing excess loss (actually radiation, not loss),
>so I'll see what I can do to prevent or at least reduce radiation.
>It's also possible that the blackening agent used in my sample has
>greater RF loss. Normally the dielectric loss in cable is not the
>dominant factor, but this may be a special case.

I've spent this morning with a swept frequency loss test, and the
screen shots and test setup is described at:

http://home.cox.rr.com/k8zoa/Zip_Cord_Loss.htm

I feel quite a bit better about this measurement. I suspect my earlier
numbers were corrupted by a ground loop.

Freq Measured Loss (dB) Loss (dB)/100 ft
5 0.4 2.3
10 0.6 3.5
15 0.8 4.6
20 0.95 5.5
25 1.2 6.9
30 1.4 8.1
35 1.5 8.7
40 1.6 9.2
45 1.8 10.4
50 2.0 11.6

For interest, the ARRL's zip cord loss measurements reported in
"Zip-Cord Antennas -- Do they Work?" by Jerry Hall (QST, March 1979,
pp 31-32) are shown below:

7 MHz 1.5 dB/100 ft

14 MHz 4 dB/100 ft

21 MHz 5.5 dB/100 ft

28 MHz 7.5 dB/100 ft

Except for higher loss values shown in my measurements below about 10
MHz, the data is in reasonable agreement. While not a great feeder,
zip cord could work in an emergency.

> Reg,
> This leads to another question.
==========
I thought it would.
==========
> But my question now is, does the
> relation
> Zo = 1016.703 / (CpF * VF)
> hold at lower frequencies where both Zo
> and VF are changing with frequency?
==========
It does not hold because Zo becomes complex
at low freqs yet both C and VF are real quantities at
all frequencies. Zo = Ro + jXo.

However, the form of the equation is correct.

When measurement units are -

L Henries
C Farads
V Metres per second
Ro Ohms

the HF approximations are -

V = 1 / C / Ro

V = Ro / L

V = 1 / Sqrt(L * C)

Ro = Sqrt(L / C)

The most accurate way of finding Zo up to VHF is to measure the
physical dimensions of a line, measure the capacitance between
conductors at LF, and then calculate it. But as we all know, 10 %
departures from expectations cause no discernible change in
practical performance.

Velocity can be measured at any frequency as accurately as distance
can be measured with a tape measure - say 1 part in several
hundreds. Time = 1/Frequency can be measured to a few parts in a
million or better.

Regards, Reg, G4FGQ

Message-ID: <3bc1cd73$0$1524$272ea4a1@news.execpc.com>
Source record: 156270

I am somewhat familiar with station grounding and single point grounding--if this means everything is tied together. What I would like to do is set up a separate operating position in my radio room--Icom on one side and old equipment on the other side. To get to the Icom station ground point would require about 12 to 15 feet of ground strap, however, I have the water pipe about 4 feet away from this station location. The service ground is attached to this pipe. Outside, the Icom station ground connects to service ground and it connects to my short tower and bulkhead. There is a cable connecting all of this to my big tower and buried radial/ground rod system.

Question: Would I run into problems with any ground loops or RF problems?

369. Modified G5RV

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-08 16:08:37 UTC
From: RadioCom <daveaa1a@fastdial.net>
Message-ID: <9psiee02opl@enews4.newsguy.com>
Source record: 156273

Best Antenna here.. After years of fooling around with various wire antennas, beams and verticals I finally can say that the best overall performing wire antenna is the 'Loop Skywire' by Dave, W0MHS, This was arrived at by accident here in consequence of hearing so many good reports about the G5RV style that I decided to build a 160m version which would be just right for me. It was a disappointment except on 40M where it was really designed and had much receive QRN compared to the vertical full wave loop. I tried to justify keeping it up but something had to go. I tried an extra 230 ft. length (1/2 wave @ 160m) of heavy wire connected to the ends of the 160/G5RV 'inverted Vee configuration' up 70' @ apex which made for a 430ft. circumference horizontal loop up about 70 ft. average. It is a little short of design length for 160 but performs just fine. The receive noise is way down just like on the other loops but performance seems to go up by the band. Ten meters may be open but I snag the weakest I can hear worldwide which is better than with the 80m loop, the 250 ft. end fed wire and even the multiband beam.. I took the 80m loop down and will remove the multiband beam and leave the 250ft. wire for use as a tuned parasitic... So, call it a modified G5RV/160/W0MHS antenna and thats where it came from, thanks to innovative hams there is always something to think over..
Am developing a few rules about antennas:
1. Never use a vertical except on a ship or at salt water or vhf/uhf.
2. Use loops if you want to have less electrostatic noise in your receiver plus some gain.
3. Use loops or wire antennas especially over poor conducting earth like here @ 02050 where silica sand is most lossey.
4. The more wire, the better. You can always attach a relay or two to get you fed more around the loop in the case of directional issues.
5. Using a compound bow and arrow with 3/8th deep socket over point will let you shoot a light weight monofilament line from a fish reel right over the top of any tree and right down the other side where you can hoist your lanyard. Forget springs, pulleys, extra lines, as the soft branches provide the spring. Don't forget to pull through back and forth from time to time to prevent the tree 'growing' around your line.
73s de Dave - AA1A - www.radiocom.net
And the best part is, it was invented right here in Marshfield, Mass. back around 1906..

Wow--what a big circle we have made! So what is the bottom line? Fan or no fan? ATR30 or AT4K? $500.00 or $1000.00? I think they both have similar capacitor sizes. Perhaps the roller inductor on the AT4K is better made. Perhaps the fan is for really high power into poorly matched antennas in nasty environments (dipole with uneven sides fed with barbwire laying on the rocks in the mountains of Afghanistan!). However, using a dipole cut for 1.840 fed with 450 ohm line, or commercial beam antennas fed with coax where there is not over 2.1:1 SWR, it would seem like the ATR30 would be the ticket--and leave $500.00 in the pocket to take the wife on a little trip too! Since I have not seen either antenna offered for sale used, I would have to guess they are both good ones and their owners are satisfied.

Rudy;
My advice would be to connect both(actually all) pieces of equipment to the same grounding point. Be careful that the ground is actually a ground and is not isolated from earth somehow.
Years ago I installed a computer terminal network using commercial IBM computers and terminals. One of the terminals was in another building. It had it's own power distribution source and it's own grounding point. This was in a heavy industrial situation and we had a 600 hp motor that inconveniently dropped off line several times. Each time the voltage spike caused by the starter points opening caused me to loose the circuit board on the remote terminal. The cause was the lack of a spike suppresser in the terminal. IBM replaced 4 of these boards at $1,000 each before we discovered the cause.
The moral is don't trust you ground to more than one point.

Try a high-end modeling program like "Math CAD" and don't forget to take the antennas relationship to the earth into account.The pattern of a loop antenna in the vertical plane looks one way but flipping the antenna 90 degrees into the horizontal position does not cause the pattern to move with it.It will change but you will find a very desirable patrtern,not one pointing straight up.TG

Jack, again congratulations on a great peice of work.

I can't help but think that these losses are so ugly as to still have some radiation effect involved, but in a practical sense, it just highlights the reality of the problem of getting the RF power to the desired radiator.

I have added your characterisation of the zip cord to my online transmission line loss calculator at http://www.owenduffy.com.au/electronics/tl/tllc.php .

Jack Smith wrote:

Indeed. Although despised by hams, ordinary TV ribbon looks better than zip, even at 3.5 MHz.

Cheers... Owen (VK1CAE)

>
Are you sure an RF station ground is necessary? (Lightning grounds,
AC/DC grounds, and RF ground planes for the antenna may be a different
matter. I am referring to the RF ground that allegedly needs to be
connected to the grounding screws.)

I maintain that RF grounding of the transceiver is NOT necessary.
According to proponents of RF transceiver grounding, an RF transceiver
ground is needed to combat noise and RF feedback. If I am wrong (as
some people will say), I would like to learn the hows and whys on RF
transceiver grounds, which nobody seems to be able to delve into. For
example, where do the noise and stray RF come from? Exactly what
happens if no RF transceiver ground is used, and how does adding such
a ground change this? What are the characteristics of an ideal RF
transceiver ground? Why does everyone advocate using an 8-foot metal
rod buried in the ground or a resonant 1/4 wavelength counterpoise
wire? Why not use a 4-foot rod? Or an 8-foot rod lying on the
ground? Or a metal gutter? Or a bundle of aluminum foil attic
insulation? Or a nonresonant counterpoise wire? Why aren't RF
transceiver grounds used on 2m and higher bands? Where is the RF
transceiver ground on a handheld unit? Why can a car or aircraft
chassis be used as such a ground? Where is the RF transceiver ground
on a satellite or spacecraft transmitter?

Why don't I consider RF transceiver grounding necessary? From what I
can tell, stray RF occurs when there is either an imbalance between
the two currents flowing through the feedline or RF current flows on
the OUTSIDE of the coax shield. The two currents of the feedline
should be of the same magnitude and flow in opposite directions in
order to complete the circuit. In the first scenario, an imbalance in
the RF currents will cause stray RF current. In the second scenario,
RF flows on the outer surface of the coax shield. Coax is intended to
conduct RF current in one direction on the inner wire and an equal
amount of RF current in the opposite direction on the INNER part of

the coax shield. No RF current should flow on the OUTER part of the coax shield. In either of the two scenarios I described, stray RF current is induced, and wierd RF feedback effects (RF-hot objects, arcing, distorted audio, etc.) happen.

If you are using an unbalanced vertical antenna, you need a better RF ground plane for the ANTENNA. This RF ground is connected to the coax shield at the antenna feedpoint. The function of the RF ground plane is to conduct RF ground currents back to the antenna feedpoint. If insufficient RF ground current reaches the feedpoint, two things may happen. There may be too little RF current in the coax shield to complete the circuit or the outer shield of the coax may be used as the RF ground plane.

It would also be a good idea to use RF chokes (or baluns in certain cases) on the coax. RF chokes add inductance to the OUTER shield of the coax. This inductance provides high positive reactance for RF currents and thus minimizes that pesky stray RF. The other two RF currents flowing inside are not affected, because the metal of the outer shield of the coax has a shielding effect that ensures that the inductance does not penetrate inside.

Hi
I am currently am using a cushcraft AP8 for 10-80. It works quite good to get around North America but I don't see to get much distance. I was looking for an additional antenna to give me some distance. I have quite a bit of acreage some size is not an issue but I don't have a rotor.
I have heard good things about the GR5. Any thoughts? I want keep it fairly simple and easy to maintain as the winters are a little rough around here.

Thanks in advance for any advise

Well,..

When putting in buried ground radials does it matter if they are insulated rather than bare wire ??

Kinda afraid to ask as it sounds pretty dumb, I guess. But if it's okay to do that than I can start on tuesday as I have several hundred feet of 14AWG insulated. I'm debating between vertical vs. vertical dipole and so radials are an issue. A fast reply tonite or early AM is mucho appreciated.

TIA,

Andrew

Andrew,

It won't matter. The insulation might just ward off corrosion for a couple more years (you didn't mention what material your wire is.)

Bottom line: the insulation won't harm anything at all. Just bury it. The more the merrier.

Why would this not work, or would it??

Say you want a 160M wire of 518 feet in length.
Take same wire, wrap it as a coil with 1/2" spacing betw'n coils
(Approx.) slap same on a PVC mast (or even staple same to a
tree !!) fire up the transmatch and work the world. Could such
an idea work? It would mean something like only a 21 ft. mast
if my math hasn't failed me. Labor intensive antenna but sure
sounds convient. If it worked you could hoist the thing up a tree
and get elevation too, I suppose. Am I missing something ???

Simplest shortest answer I can post.

Every quarter wave along a conductor, the current and voltage reverse.
The free tip end favors voltage.

Antenna radiation takes place best along the highest current portion of
a conductor.

Anything you do to shorten that by winding it up, folding it over, reduces
the effectivenesss of the conductor at radiating. The trick at shortening
an antenna is to keep as much of the current portion as straight and
properly oriented to the intended task of radiating as possible. But
any shortening .. reduces the radiation from what no shortening would
have given you.

From this point forward, the arguments get endless on the best way to
cut an antenna down to a manageable size yet still optimize radiation.
Manageable is a value judgment, it seems .... ;)

Grinning, Ducking, and Running For Cover .. GDRFC!

--> Sleep well; OS2's still awake! ;)

============================
If radials are enamelled wire it makes no measurable difference.

If thicker plastic insulated wire is used the loss/connection
resistance (which what matters) is unchanged and there is a small
capacitative reactance in series with the resistance to ground.
The capacitative reactance is tuned out simultaneously with antenna
reactance by the tuner.

So insulated wires are good for longevity !

Eureka! You've reinvented the helical antenna. Sure, it will work. How
well depends on the winding spacing, overall height, if the winding is
optimized for better current distribution, etc, etc. The ham sticks
you see on cars are this type of antenna in a small form. If you tune
the antenna as a 1/4 wave, you can likely use very simple matching or
even no matching in some cases. Multi-band? Won't be too good on other
bands other than 160m, but it would radiate a little. Too many
windings for most the higher bands. Also, with this type of antenna
it's very important to use some capacitive loading at the top, or ends
for a dipole. So you really should use a length of straight wire at
the top, or even better make a hat. A continuous helical antenna with
no loading wires at the end is usually not very good . You would
really be better off just using a random dipole with the tuner.
You will need a good ground radial system for the vertical. You don't
with the dipole. A 160m dipole fed with ladder line and a tuner would
be better on most all bands than the helical tree. A 160m loop could
do well also on most all bands. BTW, if you do decide to make a
helical, as a general rule it takes about twice the wire that it would
for a straight 1/4 wave. So you might need nearly a 1/2 wave of wire
to resonate to a certain band. For a multband helical it would be
better to make the base antenna for the highest band you work, and
then add capacitive loading for each lower band. IE: longer whip,
wire, or hat.
Not really convenient compared to just a dipole,ladder line and tuner.
MK

Hi,

Actually, it does matter. I had been working in a BBC broadcasting station in Cyprus, 10 250 Kw shortwave senders and 3 MW senders of 200 and 500 Kw. We always used bare copper wires, mostly on the surface for MW verticals, apparently this was regarded more efficient. This point was very strongly made clear when we upgraded a 30 year old tube sender to a modern solid-state unit and replaced the open-wire cage coaxial feeder with two semi-rigid air-spaced coaxials made by Kabel Metal. These were burried all the way to the gp vertical antenna far in the field, and brought to the surface near the antenna matching unit. (One was the main feeder, 250 Kw rating and the other sby, 100 Kw rating).

After a few days of operation at 200 Kw o/p, the sender begun to trip thru the VSWR protection unit, even on the sby feeder at half power. Eventually it was impossble to keep it going, even at very low power as we had continuous VSWR trips. An engineer from Kabel Metal was called and he found out that bothe feeders had a fault near the antenna end. We had to dig up the feeders from the ground to find out what happened - both coaxials were totally fried by rf heating to the extend that even the soil melted and formed nice green crystals, fused with the coax! The explanation was that RF induced on the uncovered portion leaked thru the outside protective covering of the burried coax to the ground, but because the cover is not a low-loss material, dielectric heating and losses in the ground itself caused all the damage. The solution was to replace the damaged section and ground it thoroughly with lots of bare, wide copper strips all round the entry point to the ground.

My advice is, if you can use bare copper wire radials on the ground. Burry them only if you have to, once under ground they are inefficient as the RF field has to pass thru the ground to reach the radials. Of course, even with linears its unlikely that insulated wires will burn, but there will be losses. In fact I once had a 50 W cw sender which I used with an indoor insulated wire antenna and even with the low average power of A1 operatrion, the insulator overheated and smelled badly at a point were it touched some object I don't remember.

Hope this helps.

The calculator does identify that the data points used for the models are derived from published data. Having stated that, I do not regard that I have claimed that underlying data is my original work. The very small amount of data used for the models was in my view allowed within copyright law in this country without obtaining a licence to copy.

The data for the Wireman cables was supplied to me in the form of a graph by Press Jones of Wireman who was happy that I include the data in the calculator.

To avoid misunderstandings, I have denied access to the calculator.

I hope this adequately addresses your concerns.

hi all,

I have a plan.....
my garden is 12'x27'. not much room to work 80/40.
I have just purchased a 9m fibreglass telescopic mast. I have a few ideas
on how to approach this and would like your thoughts.

1. if I run a quarterwave for 40m up and make a coil for 80 so it top
loaded. this would be about 33' of wire and the same for the coil. these
are rough lengths and I'll work out the maths later, if the ideas are sound.

2. run 66' around the entire length and this will give me a half wave on 40
(no radials ?) and a quarter wave on 80m. can I coil 66' of wire to make
radials. also will be fed against earth.

3. run the same 66' up the length and run another 66' over my roof to make a
half wave on 80m. could this be coiled at the top ? would this then make it
top loaded for 160 ? if 33' foot with a 33' coil will make it work on 80
then 66' with a 66' coil make it work on 160 ?

not too sure about option three and think option 2 would be the easiest, not
too fussed on 160 but would like to work 80/ 40 and use an atu for the
higher bands.

does anyone have any thoughts or suggestions ?

cheers
paul mw0dct

Consider establishing your common point ground at a point
outside of the home, preferably near the electrical service
point ground rod. All of your telco, power, and antenna protectors
should share a common grounding point before they enter the
home.

But that doesn't give you the right to include it inside your own copyright, which is what Wes is objecting to. I don't think you meant to do that - it's just that the wording of your copyright notice is too sweeping.

In all countries that have signed up to the Berne International Copyright Convention, copyright belongs to the originator until they dispose of it, or until it expires from to old age. In countries that have adopted the Berne Convention fully, there is no need to register a copyright - as soon as you create something, your copyright comes into existence automatically.

When Berne came into force, the purpose of the copyright notice changed. It is no longer creating a copyright but simply reminding the world that it exists, and who owns it.

>The data for the Wireman cables was supplied to me in the form of a
>graph by Press Jones of Wireman who was happy that I include the data in

>
Same applies. Unless PJ actually said he was handing over the copyright, he was only giving you the right to quote the information - not to claim it as your own copyright.

>To avoid misunderstandings, I have denied access to the calculator.
>
>I hope this adequately addresses your concerns.

It would have been better to leave the program as it was, and just claim "Program copyright..." That is also a good place to acknowledge any sources of information that are not your own.

Been there, done that, which is how I know it's so easy to make
mistakes! As my dyslexic friend so rightly says: "It's a mindfield."

Yes, we can tell you're in Britain, without looking at either the callsign or the e-mail address! My own situation is very similar.

>I have just purchased a 9m fibreglass telescopic mast.

From a mechanical point of view, take great care with this if it's a DK9SQ type. I tried one here, and although it's great for /P it didn't stand up well to permanent installation through winter gales. Some sections dropped down (had to replace one as a result) and others have jammed up. In your limited space you won't even be able to guy it usefully.

Also it isn't strong enough near the top to take the sideways pull of an end-loading wire. This will affect some of your planned options.

>I have a few ideas
>on how to approach this and would like your thoughts.

>
Probably not strong enough to carry the coil anywhere near the top, and anyway you can't literally top-load it with a lumped inductance - there has to be something beyond the coil to create top-capacitance to resonate. Either that, or the coil has to be stretched out into a section of helical antenna.

G4FGQ's program MIDLOAD.EXE would be a very good way to check what you can or cannot do with loading coils.

>2. run 66' around the entire length and this will give me a half wave on 40
>(no radials ?) and a quarter wave on 80m.

Like the guy in another thread here, you're re-inventing the helical antenna... except it doesn't actually work like that. When you coil the wire up, you change its resonant length.

>can I coil 66' of wire to make
>radials. also will be fed against earth.

No, you can't do that either (well you can, but it won't work). In your
situation you need to get out as many straight radials as possible...
and in that limited space you'll never have enough.

>3. run the same 66' up the length and run another 66' over my roof to make a
>half wave on 80m. could this be coiled at the top ? would this then make it

>too fussed on 160 but would like to work 80/ 40 and use an atu for the
>higher bands.
>
If only it was as easy as measuring out a quarter-wavelength and then
coiling it up again...

>does anyone have any thoughts or suggestions ?
>
The best I've been able to do with that situation is to mount a long CB-
type whip at the top of a 20-25ft scaffold pole, and insert either a
loading coil at that point or a shorting wire for 40 and above. The pole
is self-supporting but is mounted so that it tilts over very easily to
change bands. That plus as many wire radials on the ground as possible
(just under for practical reasons), each one as long as possible, and
earth spikes at the ends of the shorter wires.

I did consider an end-loading wire to make an inverted-L - 33ft up, 33ft
back towards the house. That requires a pole that is fairly strong all
the way up to the top (1.5in diameter minimum) and will require back-
guys to balance the pull.

This does seem to be a very British problem! Some of these ideas have
been covered in recent RadComs - see the index on the 'In Practice'
website, via the URL below.

hi ian
thanks for the help......
yeap......live in a shoebox

another thought would be base loading for 80 and running the rest up for 40. I understand this would give me less bandwidth than top loading but would solve the issue of the weight on the top sections.
guying will be half way up and 3 quarters the way up and will have three 4' scaffold poles into the ground as anchorage. I was thinking I can use these for earthling as well.

i could run 33' feet up the length and the other 33' over the roof but i dont really fancy that.

i think base loading could be the answer....any thought
cheers
paul

|copyright law in this country without obtaining a licence to copy.
|
|The data for the Wireman cables was supplied to me in the form of a
|graph by Press Jones of Wireman who was happy that I include the data in
|the calculator.

I have had some correspondence with Press and passed along some information not previously published. I have given him permission to use whatever he wants to use of it as long as he attributes it correctly. I hope that will be done, but in this case it doesn't sound like it was. I hope I am wrong. Since the numbers you have are *exactly* those that I published, I assume that they derive from my work.

Dan Maguire, AC6LA, also used the data in his EXCELLENT transmission line Excel program and stipulates where the numbers came from right in the table.

My only gripe is that you appear to claim everything on your site as yours, as if you created it. Very few of us do entirely original work; we all build upon the work of others. A tip of the hat to them is always in order. In the paper I wrote on this subject, I had 18 citations and references alone.

Besides if something goes wrong, you might even be able to share the blame<g>.

|
|To avoid misunderstandings, I have denied access to the calculator.

This is not necessary from my perspective, if the above considerations are addressed.

Mark,

Thanks a lot for your help! Yes, my antenna is an HF2V and it works beautifully on 7 MHz. Meanwhile, I have added 4 1/4 wave radials for 18.1 MHz, it works but I can't get the SWR below 1:2, while keeping the 40 m coil in line. So I'll try your suggestion to bypass thecoil and see what happens.

I tend to avoid advice from people that state they do not understand
the subject.

While some of the questions are installation specific in nature,
there is plenty of published information available that explains
the principles and rational of RF grounds and electromagnetic
compatability (EMC). Good engineering practice, as evidenced by
most if not all commercial installers, includes proper grounding
of equipment to improve safety and performance across the spectrum.

Basically that is what I have--I think. When I moved into the house, all that existed was the 8 foot ground rod for the service. The AC unit, telephone and well are also attached to this rod. (the bolts were all loose as I discovered) About 16 feet away, I put in another ground rod. I have my Icom station hooked to this rod. About 16 feet the other way from the original ground rod, I have a short tower and my bulkhead covered with Polyphaser arresters. This bulkhead has copper straps going to an 8 foot ground rod. The tower next to it has an 8 foot ground rod on the bottom of one leg. There is a cable that connects all the ground rods together. There is also a cable that runs from the bulkhead to the big tower, that has a bunch of buried radials about 70 feet long with 8 foot ground rods every 16 feet on the radials. I believe that single point grounding is just that--all connected to the same ground SYSTEM, not the same ground rod. If that is the case, then I should be OK. If not, then it is not practical for me to do and I will have to do something else! Polyphaser can advocate the single point ground system and I am sure it works in a remote repeater installation, or a commercial radio station, that is designed around it--but I can't depreciate and deduct it! Cost is a real factor in ham installations.

That may very well be the case.

What really disappoints me in all of this is that so many articles have been
written on the subject, concluding that the antenna's fractal geometry
uniquely translates into the antenna's electromagnetic behavior, yet no one
bothers to compare the fractal with other random or well known geometries
that basically behave the same.

Consider this issue from a different perspective. Although Puente and
others state that its not the self-similar fractal geometry that contributes
to lowering resonant frequency or performance as a small antenna, it is only
self-similar fractals they write about. What if I were to write a paper on
a monopole with some random bend in the middle to increase the overall wire
length. I then iterate this random bend by repeating it more times in the
monopole to further increase the overall length with each iteration. I then
call this monopole the Squirrelly Q monopole. I show that with increasing
iteration, the resonant frequency decreases, etc, etc. I then claim that
the performance of the antenna is somehow (but never show mathematically or
otherwise how it is) related to the Squirrelly Q geometry. The peer
reviewers would laugh at the article and throw it out. Now I write the

exact same article, same results, same conclusions but the geometry is a self-similar fractal. Suddenly its a new field of study that needs more investigation and everyone runs out and applies for patents.

It is also interesting that the authors claim, in the case of lowering resonant frequency, that the fractal dimension translates into the antenna's electromagnetic behavior. However, no one can tie the decrease in resonant frequency to the fractal dimension. The fractal dimension of the Koch monopole is 1.262 but this number has no correlation to the decrease in resonant frequency. Puente claims that there is a correlation but he can't define it or has not shown it. Puente even states that "The peculiar behavior of the Koch monopole must be linked to its geometric shape." The Koch monopole does not exhibit peculiar behavior nor is its behavior uniquely linked to its geometric shape. ANY antenna of ANY geometry exhibits essentially the same behavior as the wire length is increased. As one would expect, some geometries decrease resonant frequency more effectively than others. However, there is nothing unique or special about the Koch fractal geometry. The Koch monopole happens to be a geometry that is very ineffective in lowering resonant frequency.

As for the multi-band behavior of the Sierpinski gasket, the authors do almost the same thing. The authors present the performance of the gasket through several iterations, demonstrating that it has multiple points of low return loss and then conclude that this behavior is directly a result of the self-similar geometry of the gasket. There is no comparison to another gasket of the same size with an arbitrary or non self-similar arrangement of holes. As I said, I'm still working on this one, so I don't want to go much further, yet.

I agree with George. My experience has been good with a delta loop in horizontal configuration. Have used an 80 meter in both the triangle and square configuration, did not notice a lot of difference between them. I fed the system using a radio works 4:1 balun and RG213. The 30-10 meter bands were very good for dx, 80/40 so so, I have played with the modeling not sure it tells you a whole lot on how they will actually do, but on the air test show they work well. Rudy wrote:
"Polyphaser can advocate a single point ground system---."

If you have a 200 000 amp lightning surge flowing through 20 ohms impedance between grounds 16 feet apart, the voltage drop is 4 million volts. Can your Icom take it?

On the other hand, if everything is grounded to a single point, the voltage goes up and down on everything together and the voltage difference between devices is zero.

Maybe you can afford single-point grounding after all. Single-point grounding does not rule-out multiple grounds. It means devices don`t share ground wires but the individual device ground wires all connect to a single point.

Best regards, Richard Harrison, KB5WZI

Steve:

Interesting ovservations below... I've noted that such exagerated claims and hyperbole from "fractalists" is apparently not limited just to the design of antennas... I have noted this kind of hyperbole from "fractalists" in several fields of endeavour... [Heh, heh... fractalist... now that's a good name for fractal protagonists.]

What drives such hyperbolic behaviour?

Personally, I believe it is the result of the "publish or perish" paradigm applied, perhaps too harshly, to our academic bretheren...

Since the "invention" of fractals by Mandelbrot a couple of decades ago, and the popularization of fractals by such as cover articles in Scientific American, we have seen cream skimming, opportunistic "fractalists" rushing into various fields and making hyperbolic claims of optimality with many early but inconsequential publications couched in obscure and obtuse language and hyperbolic claims. The obscure/obtuse language seems calculated so as to overpower, and thus sidestep, the usual "peer review" panels normally available to technical editors. Where can you find reviewers willing to spend the time and energy to learn all kinds of new "lingo" for old ideas.

[Incidently as you already know Mandelbrot himself did not invent fractals...fractal behaviour has been known for centuries, just "unamed". We used to call them "limit cycles", many many years ago, but I guess the name "limit cycles" was not obscure enough to create publishing opportunities for the "new gurus" or fractalists trying to get around peer review panels.]

IMHO... Areas where... often inappropriate application of fractal ideas have popped up, and these are only those that I happen to be familiar with, which come to mind are: Antennas, Data compression, channel encoding/decoding, noise generation, packet data traffic simulation, etc...

I am sure there must be others. Most of the early claims for the superiority of fractal techniques applied to these fields have proven to be hollow.

As I see it, fractal geometry when presented in 2D or 3D computer drawings are "pretty" and certainly suitable for printing in four color glory on the cover of Scientific American, etc... and they are mildly interesting from an abstract mathematical viewpoint. But certainly not to the level of the theory of groups, etc... but that "beauty" alone does not make fractals the "optimal solution" to any problem!

As near as I can tell, most of the early publications of "fractalists" who opportunistically applied fractal techniques to these various fields, have always inappropriately and without proof, touted them as "optimal" or "the best" or "key" with no tangible proof! However they did get one or two more papers to add to their academic curriculum vitae. Those inconsequential publications alone represent a few "beans for the pot" in the preparations of fractalists for dining at their final meal of academic tenure!

Another area of exagerated hyperbole is that of the theory of "wavelet", techniques. Wavelets are interesting and have certain advantages in some specific applications, but as with fractals, wavelets have no where near the ability to live up to the "hype" of early protagonists. Still we are all subjected to this barrage of unwarranted claims.

Like you I believe that exposing some of these ideas to the free and open critique of the USENET NG's will add greatly to the enhancement of the often pathological absent traditional scientific/engineering academic peer review process.

Hyperbole needs to be questioned in public fora. Not in private cliques!

Thoughts, comments?

I use a B&W AP10 apartment antenna for portable requirements. It works reasonably enough, and by moving a tap on the coil, and tuning the counterpoise it will operate 40 through 2 Mtrs. The mount will clamp on a door, the bottom of a window, or a table top.

There is info on their website. I gave about $90 for it at a Hamfest.

417. Portable 10-40M Vertical?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-09 22:22:16 UTC
From: Richard <2e0avf@talk21.com>
Message-ID: <9pvt9p$6mc$1@plutonium.btinternet.com>
Source record: 156319

Hello

I would like some information about verticals that cover 10-40M and can be broken down into small lengths so that it makes it easier to carry it for portable use. If anyone has been away and operated using a vertical I would like to know how you packaged it so that it can go on a plane. After reading I see that most people use ski bags as they are tall and you can get a decent sized vertical into it.

Looking for a fairly cheap antenna but with good performance that can be broken down for portability, either bought or homemade. I did think that it might be an idea to use a 10-20M vertical and use a dipole or wire antenna for 40M so that the antenna will be smaller overall but open to ideas for a setup.

I will be operating from a fixed location(at a house), so will be able to use radials. Not sure if any trees are near by to hold up wire antennas so I thought that the vertical could act as a pole for a wire antenna if I go with that setup.

Comments or help would be great

Richard

What does "single point" mean?

Does it mean that I should run a wire 250ft from the equipment out
back one side of the house to the service ground out the other side?

If so... Now what happens if I add a ground rod right next to the
equipment and connect that 250ft wire to the added rod without
disturbing any other connections?

As another poster has noted, the mechanical problems of Twin Lead are not worth
the grief.

Years and years ago, the wire companies used to make heavy-duty "transmitting"
Twin Lead that was much heavier duty than the TV ribbon we have today. Coax so
dominated the market that the transmitting stuff disappeared.

I am curious as to what advantages you see in the multi-folded-dipole. Is this
the result of simulations?

The mechanical troubles are the real problem. A "theoretical" dB or two makes
no practical difference in this sort of HF antenna if the durn thing won't stay
up!

--

Might I suggest three different solutions:

1) Center-fed inverted V using open line feed and a tuner. The overall length
of each leg can be whatever you can fit - the more the better. This setup will
permit you to use all bands including 17 and 12 from 40-10, and it may even
work OK on 80. You need a proper balanced tuner, however.

With your layout of a 70 foot ground space, 45 foot feed point apex and 25 foot end poles, simple geometery predicts that each leg could be as long as 40 feet (80 feet of wire overall).

2) Coax-fed the trap dipole. Using 20 meter traps made of a 25 pF transmitting cap and an appropriate 4.7 uH inductor (Miniductor is great) you can cover 40,20 and 10 with low SWR.

3) Triangular loop, fed at the middle of the bottom. This loop will be at least a full wave in circumference on 40 meters. I'm not sure how well it will work - you will want to run a few simulations before deciding.

>you!

The book formulas are only a starting point. They work fine if the antenna is up in the clear and there are no interactions, but in practice one almost always winds up doing a bit of cut and try with wire antennas of this sort. (actually, more like "cuss and try"). This fact is one of the reasons the ladder-line-fed dipole is so popular - you just put it up and let the tuner deal with the SWR. At worst, you may need to trim the feedline length a bit.

Your eather seems to be more conductive than mine, although I don't see any way to relate your measurement of braid outer current to the inner current from what you posted. In the experiment I ran earlier, with the coax load being only a resistor between center and outside at the end of the cable, I found a differential:common mode ratio of approximately 366:1. How do your measurements of common mode current compare with the differential current or other known quantity?

Roy Lewallen, W7EL

---- Part of a posting made on rec.radio.amateur.antenna
on May 1, 2001, subject "What's the difference. . . ----

This afternoon I ran the following experiment. I made a current probe by winding 10 turns on a high permeability ferrite core of about 1 inch OD. The impedance of one turn on this core at 10 MHz was measured as 7.3 + j2 ohms. The winding was connected to 4-1/2 feet of RG-58, then run to a scope input which also had a 50 ohm termination. An ideal current tranformer with these turns and termination would have a sensitivity of 5.0 volts/amp. This probe measured 4.43 - 4.74 over the range of 1 - 30 MHz, and 4.83 at 10 MHz where the remaining measurements were done. Currents shown are relative; to get absolute values in amperes divide the values shown by 4.83.

A 2 foot piece of RG-58 was connected as follows. The shield of the input end was connected via a short (about 1/2") pigtail to a piece of solid plated PCB material. This point is defined as "ground" in the

experiments, and all ground connections are to this single point. A signal generator was run to a BNC connector grounded at "ground", and the center conductor of the connecter was attached to the center conductor of the input end of the 2 foot coax. The voltage at the input end was used as the phase reference. In retrospect, I didn't carefully measure the phase of the current probe output relative to the indicated voltage, except to note that it was close to zero. So the current phases should be regarded as also being relative.

As a first test, a 51 ohm resistor was connected between the shield and center conductor at the output end of the coax. No other connection was made to the output end. The current through the 51 ohm resistor was measured, and the current on the outside of the coax was measured. This outside current was measured by running the whole cable through the current probe core. For a resistor current of 0.366, the outer shield current was 0.001. This shows that 1. All the current coming out of the center conductor at the load is flowing back to the source via the inside of the shield, and 2. The current on the inside of the coax shield is not visible to the probe.

You should terminate the current transformer with a low, not high resistance, otherwise its impedance can disturb the current you're trying to measure. The impedance the core presents to the line you're measuring is R/(N^2) where R is the terminating resistor and N is the number of secondary turns. This will be in parallel with the core's intrinsic impedance. Fortunately, the impedance of a type 61 core isn't too high. On the other hand, it doesn't make a very good transformer because its relatively low Z reduces the accuracy. A better choice at HF is a 70 series or type 43 core, terminated with a small resistance. I like to use 50 ohms for the termination because then I can use coax between the transformer and scope without encountering a wild frequency response.

If you can squeeze in a 78ft antenna then one good choice for a
10,15,20,40,80m dipole is the W9INN MPD-5C. Bill (W9INN) has an
informative web page at the web site listed below.

I have had the MPD-5C up for over 5 years and 298 DXCC countries later it
is still going strong.....

You have to work with what you have sometimes. Bonding
two ground rods 16 feet apart is in accord with electrical codes,
but you do lose some lightning protection because of the
series reactances of the bonding wires.

At a minimum, consider a second ground window at the
operating position, where all of you coaxial braids, and
some additional AC and Telco line protectors share a
common bonding point. This isn't so much to establish a
"ground", but to instead to further minimize paths
through the equipment
because of differing potentials between your power sources
and antenna feeds.

|to take into account the fan or parallel arrangement I have planned?
|Having three antennas fanning out in parallel *must* affect impedence
|and resonant frequency, but how? Please, any aid with incorporating
|these three design formulae will be a great help. I hope I have stated

|my problem clearly and with a minimum of babble. Help, help, and thank
|you!

Attempting to calculate this is going to get you almost nowhere. If you can indeed 'fan' the individual dipoles to place them in different azimuth directions, then I would (and do) use standard dipoles, electrically in parallel at the feedpoint and use a balun (W2DU or 'choke' type) and the best coax you can afford.

The greater the angle of separation between wires, the less interaction you will see. Start your pruning with each wire too long. Adjust the length of the lowest frequency wire first and then move to the next higher.

Happy trimming.

Wes N7WS

You need the coil on 17m. Have you made a 17m loading coil? That is
what you would want to bypass when on 40m. You shouldn't have any
matching for 40m. or at least I don't see why you would. They may use
one for 80m though. Dunno.
When on 17m , the antenna need to be tuned to a 3/4 wave resonance. So
you would add a small loading coil at the base to get a good match. MK

Hi there. I'm using a mobile rig as a base station. I need to convert AC to 13.8VDC. My question is, would it be ok to use a 12V power supply? The specs in the radio's manual say supply voltage to be 12V(+/-15%) so I'm assuming this is ok but I want to make sure before I go out and buy one. Also, anything else to look out for, or can I just get a fairly inexpensive one (as long as it runs at the correct amps)?

Thanks in advance!

Julia

by the way, I'm new at this whole ham thing... :)

> trying to measure.

I had a 110 ohm terminating resistor but was having trouble
overcoming the diode drop at low power so I raised it to 110k.
110k/(20*20) = 275 ohms which is low compared to the choking
impedance of my choke.

Given that the pickup's impedance disturbs the current, the
results are still relative. What do you think about my finding
that (in my antenna system) common-mode currents seem to be
minimized by a differential Z0-match?

The so-called 12v supply is really the same as the 13.8v. To make a good base station, the main thing to be sure of, besides having enough amperage, is that you get a "regulated" supply, and it is a good idea to have it fused.
THe proper choice will depend on the rig. Just what rig do you have?

Bill-W4BSG

Non resonant folded dipoles can act like dead shorts when they are
paralleled which is not true for non-resonant single-wire dipoles.

|paralleled which is not true for non-resonant single-wire dipoles.

Well, there not dead shorts if they're made of twin lead and it's raining<g>.

Hi,
low-band antennas in restricted space is a common problem (not only in Britain). Perhaps the antennas at http://hem2.passagen.se/sm0vpo/antennas/balcant1.htm and http://hem2.passagen.se/sm0vpo/antennas/balcant2.htm can help you. Sorry, I personally have not tested them, but you can put specific questions to the author at the messageboard http://members3.boardhost.com/sm0vpo/ .

Hi Jim, et al.

The advantage(s) I see with the twinlead folded dipole are several. I plan, in any event, to run a parallel dipole, one set of wires for 40/15, one for 20, and a third for 10. I am going this route because I have had poor results with ladderline feeding a 66' V/flattop up till now, at least using the MFJ901B tiny tinuer I have (not likely to be able to get anything better for several months at least). I was going to use 75-0hm twinlead to feed three 12 AWG insulated THHN dipoles, but the problem arose of hooking it to the tuner. My balun is 4:1 current/choke type, and thus I would get 18 or so ohms on the other side of the balun. I figure than 300 ohm twinlead matched a folded dipole nicely, and then transforms to 75 ohms on the other side of the balun, easily matched by my tuner. Coax is out, since I have been persuaded in my reading that a single random length of 75-ohm coax seldem, if ever, really matches several parallel dipoles, nor does it match the 40 wires on 15 that well. Plus, I want to use parallel feedline so that I can feed *both* wires against ground as a vertical for 80. Can't do that with coax, can you? I am getting close to a workable way of securing the ends durably, and think with continued advice and experimentation, I can work out a center connection that will stand up for a few months at a time. I know it will fall eventually. If I can get it to stay up there for >3 months at a time, I'll be happy. Thoughts?

OK, so I am re-thinking now the possibility of the "random" doublet fed with 450 Ohm ladderline. I can realize *maybe* 75 feet, in a V configuration of 100 degrees, a little more with a 90deg. included angle. At my last QTH, I could not get a 50' low dipole (15' above ground, 5' off the roof) to load on 40 or 20, and it was deaf as a stone. That antenna worked better when I fed both sides of the line as a random wire agains a 6' ground pipe w/o radials. Maybe this QTH will be different (more height for one thing. . ., much more). How can I get an idea of the input impedence at various frequencies of a given V or flattop fed with a given length of 450 ohm line? I have a cheesy MFJ 901B tuner(250 pF--14 uH -- 250 pF), all I can afford for now (though I have been thinking of paralleling some more cap. at the output, and changing one of the switched coil taps to some braid and a copper ally clip, might help with range and sharp tuning, yes?) Formulae? Thanks.

What about *resonant* folded dipoles? I proposed putting up one each for 40 (and operated harmonically on 15) , 20, and 10, in parallel with one feedline. And BTW, why would a nonresonant FD act like a dead short? Thanks.

A 12 vdc supply will run the mobile rig fine as long as it has sufficient amperage and is well filtered. If you are going out to purchase one, take a look at the Astron line. These are great supplies, very reliable, clean output, and well regulated. They are actually around 13.8 vdc out of the box, but can be user adjusted between about 10-15 vdc.

If you are going to run a typical 100 watt rig I would suggest at least a 35 amp unit. It's always better to get a larger supply than you anticipate needing now (personally I always buy the biggest one I can) to provide for powering accessories and additional rigs you may acquire at a later date.

You might want to check out this link for info on the different Astron models, as well as the best prices I have found (I have 3 RS-70M models myself):

Has anybody had any success with magnetic loop antennas? I'm considering geting one and either getting it just above the roofline on the second floor or in the attic. This is one of my only choices for an antenna as I have little space to put an antenna on my lot and some cc&r's that I may not be able to avoid although my neighbors don't seem to be respecting them).

Thanks and 73!

Angelo K6ICU

> cheers, CAM, W5DXP

I can't draw any conclusions until I convince myself that you're measuring what you think you're measuring. Just how big is the common mode current to begin with? If you're reducing it from, say, 0.1% of the differential mode value to .01% of the differential mode value, I'd say that no conclusions can be drawn from it.

You say that 275 ohms is low compared to the choking impedance of your choke. Did you make all measurements with the choke in place? I was under the impression that the initial measurements were made without it. What is the choking impedance of your choke? What's the impedance of the type 61 core by itself (that is, the one being used for the current transformer)?

I would suggest you try antennas like a Screwdriver or Texas bugcatcher.
These are fare more efficient and almost unobtrusive. If you have a metal
clad building they seem to work far better than most magnetic loops. There
is a a excellent Application Note on magnetic loops on Elecrafts web page.
www.elecraft.com
You can also check www.ac6v.com
under antenna projects for more links and software for magnetic loop
design.

It isn't as efficient as loading higher up, but it will certainly get
you on the band, and make band-changing easier. The key is a really
hefty, low-loss inductor... which is no problem if it's close to ground.

G4FGQ's programs will help you to scope out the problem and explore your
options: www.btinternet.com/~g4fgq.regp/

First off let me say congrats and welcome to ham radio. I didn't see where you posted a call sign so I am assuming that you have one and you all know what happens when you assume. Anyway on to the power supply question. The 12 volt supply is actually an arbitrary number, most supplies including your cars provide 13.8 volts. My bench supply is variable from 0-15 volts Get one that in that has a higher constant amperage rating then the rig will actually draw. Say you have a 2 meter rig that draws 7 amps at 50 watts out. You would need atleast a 10 amp constant power supply. This helps keep thing a little cooler in the supply although it will still get hot and heat is equipments worst enemy. If you plan to upgrade and get a bigger rig or add things that need the power supply for instance a TNC for packet operation on VHF you might want to get a little larger supply. I guess what I am saying is get the heaviest duty power supply you can afford because there will come a time you will want to upgrade or add an amp or what ever. In my case I bought the Alinco DM-340MV 35 amp constant 40 amp surge for 149.00 new from HRO and it was money well spent. This power supply has dual metering (one for volts and one for amperage draw. One set of High amperage terminal posts rated at 35 amps, one cig lighter plug rated at 10 amps and 2 spring clip hookups rated at 6 amps total. HRO will ship for free for purchases over 100.00 and that is a HUGE savings in the case of a power supply. The weight on mine is around 30 pounds so shipping would have been pretty expensive if that had not been the case (free Shipping from HRO). The price from HRO is still around 149 or 159 dollars and I would buy another one should I need to add another pwr supply to my station. Again congrats and I wish you the best in your ham radio career.
73 and all the best

Reg:

Heh, heh... Yes! I have been affected.

Back when I was an "innocent" new participant in this august RRAA NG, after one or two of my first timid postings, wherein I was simply asking elementary questions, of what appeared to be a famous guru, about a new technology, I was treated very roughly and with seeming contempt by that prominent "fractalist".

Aside: --This fractalist shall remain anonymous, so that I can avoid threats of litigation, but I can share with you that her initials were NC! --

At the time, I felt that such disrespectful and contemptuous treatment of an admiring newcomer, who was approaching a new subject with eager questions, was completely uncalled for. I was publicly humiliated and felt devastated! What?

Subsequently during extended intercourse with said eminent fractalist here on the NG I learned that my own seemingly outdated and meager knowledge and skills in electro-dynamics, my own presumption by the way, actually far exceeded that of the "Ivy League" educated eminent Doctor of Fractals...

And so... because of such shabby treatment upon my person back then, I feel that I have been permanently affected.

I now consider that I am "in recovery", and I don't know if I will ever be the same trusting naive eager student of technology that I once was.

Best Regards,

It took me about 15 years of scrounging through flea markets before I eventually found an "inexpensive" one (20A, Cdn$35). I had to use car batteries and chargers for many years since nobody would let their power supplies (12~13.8V, 10+A) go for less than about Cdn$100.

Good luck.

Rudy wrote:
"Polyphaser can advocate a single point ground system---."

If you have a 200 000 amp lightning surge flowing through 20 ohms impedance between grounds 16 feet apart, the voltage drop is 4 million volts. Can your Icom take it?

On the other hand, if everything is grounded to a single point, the voltage goes up and down on everything together and the voltage difference between devices is zero.

Maybe you can afford single-point grounding after all. Single-point grounding does not rule-out multiple grounds. It means devices don`t share ground wires but the individual device ground wires all connect to a single point.

Best regards, Richard Harrison, KB5WZI

While we all need at some point to declare "good enough" and move on, I
can't help pointing out the obvious, i.e., even if you divide Richard's
resistance number by 100, you still have the following:

<restated>
If you have a 200 000 amp lightning surge flowing through 0.2 ohms impedance
between grounds 16 feet apart, the voltage drop is 40 thousand volts.

Roy Lewallen wrote:

> I can't draw any conclusions until I convince myself that you're
> measuring what you think you're measuring.

I'm obviously detecting common-mode current, just maybe not very
accurately. The pickup loop is itself furnishing some choking
action. But compared to my W2DU choke, that choking action should
be negligible. In any case, the common-mode current in my antenna
system seems to be minimum when a differential Z0-match is achieved
and rise on either side of the Z0-match. If true, this seems to have
some implications for hams who operate their 50 ohm chokes into random,
unknown loads.

> You say that 275 ohms is low compared to the choking impedance of your
> choke. Did you make all measurements with the choke in place?

All of my original measurements were made with the choke in place.
It didn't occur to me to measure without the choke until Richard
Clark suggested it. One choke is ten turns on an FT-240-61 core which
calculates to be 777 ohms inductive at 7MHz. My main choke is 24
FB-77-1024 beads ala W2DU style. According to Amidon, that should
be about 5000 ohms resistive at 25MHz. However, it seems to be
considerably lower than that on 7MHz, maybe around 2000 ohms.

458. FYI: Roberts Antenna Info

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-10 14:05:04 UTC
From: AC6V <ac6v@amsat.org>
Message-ID: <3BC45590.1B48C73D@amsat.org>
Source record: 156360

Received these answers from the news group -- sci.electronics.equipment
-- as follows.

The "Roberts" antenna is basically an adjustable dipole with a coax
balun
matching section. It is used by RF measurement labs because it is called
out in
the measurements methods section of FCC part 15, CISPR 22 and other RF
standards. Most labs have an assortment of these antennas, since it is
impossible to calibrate a single Roberts antenna for the range required.
For
30Mhz to 1Ghz, which is the usual measurement range, it takes about 6
antennas.
The dipole elements are made out of regular telescoping antenna
sections, and
are adjusted exactly to the frequency in question. (Stanley makes a
steel rule
calibrated in Mhz.) Each Roberts antenna must be calibrated and have a
chart
indicating losses vs frequency, since the balun cannot be a perfect
match
throughout the range.

Normally, a broadband antenna is used for most measurements, and
anything that
is closer than 6dB to the limit gets measured individually with a
Roberts
antenna.

I don't know where the name came from. Most of the labs I use have made
their
own Roberts antennas from the data supplied by the FCC.

That's probably more than you wanted to know.

Doug Moore
==========
Check out EMCO and other suppliers of EMC test equipment. Antenna
Research,
etc.

The ones I've seen are just what it says, dipole antennas. Like a pair
of
opposing rabbit ears, or whip antennas. Just picture the adjustable
antenna
on a walkie talkie, now mount two of them opposing and you have it.

They are mounted with a balun that converts the balanced signal to a
single
ended signal (50 ohm coax) They perform very close to the calculation
of
predicted sensitivity and are therefore desirable.

The signal they receive is easily converted back to v/m received fields.

Don't remember the conversion factor for a Robert's antenna, though

The dipole arms are always "adjusted" in length to be quarter wave
length of
the frequency of interest. Most of the ones I've seen cover the range
of
30MHz (where they are quite large) up to 500MHz. (where they start to
look
small)

I'm not sure if they go up to 1 GHz, or not. It's just I've never had a

need to measure anything up there.

- Robert -

Hi Will, you idea will NOT work. The feedpoint impedance of the 40m folded dipole when driven by a 20m signal can be as low as 5 ohms according to EZNEC. Thus on 20m, almost none of the power will flow into the 20m folded dipole and virtually all will flow into the 40m folded dipole with an SWR of 60:1 on the feedline. Harmonically related folded dipoles cannot be paralleled with the expectation that they will be functional. The advantages of paralleling single wire dipoles does NOT extend to folded dipoles.

EZNEC sez that the feedpoint of a resonant folded dipole operated at

double the frequency can be about 5 ohms, close enough to call it a
dead short. This is the opposite of a single wire resonant dipole which
exhibits a feedpoint impedance of thousands of ohms at double the
frequency. You simply cannot parallel harmonically related folded
dipoles and expect any performance at all because a one wavelength
folded dipole is virtually a short circuit. The 40m folded dipole
can be close to a short circuit on 20m and 10m. The 20m folded dipole
can be close to a short circuit on 10m. It's a terrible idea.

461. Problem with 2m antenna tuning

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-10 14:32:15 UTC
From: D&K Rushworth <rushworth@iprimus.com.au>
Message-ID: <3bc45c05$1@news.iprimus.com.au>
Source record: 156363

I've just built a 2m 7 element Yagi with gamma match. The antenna tunes down to 1.2:1 at 144MHz, 1.5:1 at 148MHz whilst pointing to the sky with the reflector on the ground. However, once up in the air, the SWR changes to 2:1 at 144, 3:1 at 148MHz. The antenna is vertical mounted on a 6' length of wood dowel.

Any ideas as to the large changes?

How can I tune up reliably on the ground and then install on the mast. It is a major hassle lowering the mast to make changes?

Thanks in advance.

David

Source record: 156364

I explained why I don't believe RF transceiver grounding is necessary. Although I have seen people refute the need for RF transceiver grounds, I have not heard any good, detailed rebuttals from the RF transceiver ground proponents. You disagreed with my explanation, but you don't explain your views.

My questions again:
1. If the stray RF isn't the result of unwanted RF currents on the outside of the coax shield or an imbalance in the feedline currents, then WHERE DOES THE STRAY RF COME FROM?
2. Why wouldn't improving the RF ground plane (at the FEEDPOINT) of a vertical antenna remedy RF feedback problems? This should have several benefits: more RF ground current reaching the outer shield of the coax (thus averting the imbalance resulting from a shortage of current here) as well as less RF ground current flowing through the outer part of the coax shield.
3. Why wouldn't adding RF chokes to the coax (which creates inductance and positive reactance) remedy RF feedback problems by greatly reducing the unwanted RF current flowing on the outer surface of the coax shield?
4. Why must the ground rod be 8 feet long and not 6 or 4?
5. Why must the ground rod be buried? Why can't it lie on the ground?
6. Why must we use a ground rod? Why can't we use a metal gutter? Aluminum siding? A metal window frame? The kitchen sink? A sheet of aluminum foil attic insulation? Or some other metal object?
7. Where is the RF transceiver ground for a handheld radio? Adding a tiger tail provides a ground plane or the "other half of the dipole". Does the tiger tail satisfy the RF transceiver ground proponents?
8. Where is the RF transceiver ground for a mobile station?
9. Where is the RF transceiver ground for a satellite, spacecraft, or aircraft transmitter? I've never seen 8-foot buried rods or 1/4 wavelength counterpoises attached to these stations.
10. Where is the RF transceiver ground for VHF, UHF, and microwave frequencies? According to RF transceiver ground proponents, the ground rod has to be far less than 1/4 wavelength from the transceiver. 1/4 wavelength is only about 20 inches on 2m, 6.7 inches on 70 cm, and only 2.5 inches on 23 cm.

465. Vertical Decisions

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-10 15:59:33 UTC
From: rock_bustin@yahoo.com
Message-ID: <879bfb06.0110100759.a125c00@posting.google.com>
Source record: 156367

Greetings,

For me, putting up an antenna means firing the old sling-shot over a backyard tree. Yesterday I got lucky and managed all but the ultimate placement for my backyard: 70ft. straight up an old elm tree. I've already got a wire vertical of approx. 66.5 ft up with RG-58 coax feed and 7 odd-length radials laying on the ground. BUT,... everything is still changable and I could easily haul other stuff up or add to existing. I already have a 20M hor. dipole and an old random on other trees. My question is: What is the best use for this lucky placement?

Initial testing using a MFJ-259B have not totally wowed me on the vertical although agree to need for more radials. (Do I care about radial length all that much??) - I have more wire to EMR the earthworms with. Would there be any advantage to switching to top-loading ??

A 20M or 40M vertical dipole is a possibility -- would I see better DX or signal reports over the horizontal ?? My horizontal started out as 40M 1/2wave and did great on 15M, 40M and 80M, but poor on 20M. Most SSB DX I hear is 20M so I (regretfully) cut the wire down to tuner 20M better.

I suppose Inverted "L" is also possible but may not be room for 130+ ft. needed to try 160M. So not sure of advantage.

In short, got some great placement and best elevation I'll ever get without tower -- what to do with it? If a vertical then I need to bury those radials quickly before ground freezes or XYL see red. Hope for spme reponse today/tonite if possible. Ultimate usage will be by FT-980 with occasional FL-2100B amp. and Heathkit SA-2040 Tuner.

73 de KG4JBM/ Andrew

I have never measured the performance of the AT4K.

I have ran several ATR30's, and they handle at least 4kw carrier for
long periods.

The only problem you might run into is the length of the
antenna/feedline can be a bad combo.

160 has the most restricted matching range, from about 10 ohms to
several hundred ohms. While it is wider range and much more power
handling than the Nye Viking tuner, you can easily get some nasty
impedances. I ran into this with a friend of mine, who was using a
Drake tuner on 160, and he had.to add a bunch of feedline.

Avoid 1/4 wl long open wire feedlines with 1/2 wl long antennas, and
1/2 wl long feedlines with full wave long antennas!

I've never measured a Pal-Star, but it would be easy to calculate the
matching range knowing the component values if anyone has them (and
assuming the numbers are accurate).

If you use a rational combination of length in feedline and antenna,
you should not have a problem. Higher bands are much less concern than
160.

You are arguing averting imbalance for a ground plane design? Poor
choice of words leads to poor questions and poorer answers. The first
sentence was enough, those that follow only add confusion.

>3. Why wouldn't adding RF chokes to the coax (which creates
>inductance and positive reactance) remedy RF feedback problems by
>greatly reducing the unwanted RF current flowing on the outer surface
>of the coax shield?

Inductance and positive reactance are redundant. I presume you are
speaking of RF Toroids which in turn add reactance (resistance far
more so) and thus constitute chokes. Or you could be speaking simply
of the coiled transmission line. Either will serve to accomplish what
you suggest.

>4. Why must the ground rod be 8 feet long and not 6 or 4?

Check with your coding authority.

>7. Where is the RF transceiver ground for a handheld radio? Adding a
>tiger tail provides a ground plane or the "other half of the dipole".
>Does the tiger tail satisfy the RF transceiver ground proponents?

Don't know about the tail (which would probably be another redundancy)
but have you considered that the handheld has a chassis (or metal
frame) that does this job as well as any metal? No one really expects
a handheld to observe the design goals of a base station. When was
the last time you checked the VSWR of your rubber duckie? Please
submit a plan as to how you would accomplish this feat without
changing the characteristics of the system by inserting the meter.

>8. Where is the RF transceiver ground for a mobile station?

Shielding is obvious, ground is where it has always been (look down).

>9. Where is the RF transceiver ground for a satellite, spacecraft, or
>aircraft transmitter? I've never seen 8-foot buried rods or 1/4
>wavelength counterpoises attached to these stations.

Your lack of exposure is not a compelling argument. The artificial
complaint of a lack of 8 foot buried rods in space is obtuse and
unrelated to any technical consideration not already satisfied.

>10. Where is the RF transceiver ground for VHF, UHF, and microwave
>frequencies? According to RF transceiver ground proponents, the
>ground rod has to be far less than 1/4 wavelength from the
>transceiver. 1/4 wavelength is only about 20 inches on 2m, 6.7 inches
>on 70 cm, and only 2.5 inches on 23 cm.

According to "RF transceiver ground proponents?" This is called a
strawman argument as are most of these enumerated fantasies. Ground
is handily found within the distances you describe in most common
applications. For VHF/UHF, as you have identified, earth is so far
away as to be unsuited for grounding requirements already satisfied by
the case of the equipment. So far away that it does not even present
Common Mode issues by and large.

Hi Jason,

You are taking the wording and application of "ground" too literal, and obviously for the rhetorical advantage, not for the purpose of illumination. Far too many of your "questions" dismiss (or are entirely ignorant of) the fundamental safety issue of grounding.

For those that lack your education, they may wonder at these issues too and come away with your skewed idea of what ground is (and as many who have difficulty with Common Mode, this problem is already too widespread).

Ground is not simply an aggregate of dirt and rocks, watered to aid in matching monopoles (an unbalanced design - when we speak of ground in the context of antennas). In Electronics, ground has always meant a reservoir of free charge. It also implies the sink from which all current arises and returns to. If in the isolation of space this constitutes one pole of a battery, so be it. If this same sink has competition for supplying or sinking current, then there is some issue as to which of these serves the capacity of ground and we begin on the first problem of Common Mode issues.

Even the monolith of terra firma ground does not supply a uniform and constant potential sourcing/sinking capacity. At two separate points on earth, there is almost guaranteed to be a potential difference (which flies in the face of the meaning of ground). All along the distance that spans these points, the currents may all combine to 0, but if you choose two points in isolation, this is unlikely. This is why code demands all points be bonded by a continuous wire.

> different (more height for one thing. . ., much more).

It's not just height that matters, but distance from surrounding
objects that would affect the antenna. Any sort of metal (wiring,
plumbing, rebar, siding, roofing, ductwork, insulating foil, etc.) in
a building has a profound effect on how a nearby antenna works. This
effect is why some indoor and attic antennas work well and others
don't.

>How can I get an idea of
> the input impedence at various frequencies of a given V or flattop fed with a
> given length of 450 ohm line?

Antenna simulation software like EZNEC2000 and Reg Edwards' DIPOLE1
will do the job. EZNEC2000 is general purpose, and the demo version is
free. Once you get the hang of it, it's wonderful. DIPOLE1 is specific
to dipoles, and the results with an inverted V will not be as
accurate, but it will give you a general idea. DIPOLE1 is quick and
easy to download and use.

>I have a cheesy MFJ 901B tuner(250 pF--14 uH -- 250
> pF), all I can afford for now (though I have been thinking of paralleling some
> more cap. at the output, and changing one of the switched coil taps to some braid
> and a copper ally clip, might help with range and sharp tuning, yes?)

The tuner isn't the real problem. L and C are fine unless you want 160
meters. Of course, with some good parts you can build a much better
one.

About 30 years ago, there began to appear tuner designs based on the
idea of a widerange UNBALANCED network feeding a powdered-iron or
ferrite core balun. The idea was to make a universal device that would
feed balanced or unbalanced loads and not require coil or tap changing
or switches. The designs all "work" in that they usually permit a
match to be obtained and contacts to be made.

The trouble is the balun. The designs all assume that the balun is
some sort of magic device that simply transforms the balanced

impedance of the line to an unbalanced impedance, which is them matched to 50 ohms by the tuner. In some cases this is true, such as when the balanced impedance happens to be mostly resistive and close to the balun design impedance. But in many cases the impedance to be transformed is very different from that which the balun is designed to handle, and the result is loss in the balun and tuner, fussy tuning, "RF in the shack", and poor results.

If you put up a dipole/feedine setup whose feed impedance is too low or too high, you'll have these sorts of problems. That's why simulation is needed.

Also take a look at W6RCA/W5DXP's website. Note the effect even minor changes in feedline length can have on the "shack-end" impedance.

The "best" answer is a true balanced tuner, as presented by AG6K and others. Search google for detailed discussion of this topic.

A DC voltmeter with extremely short leads across a filter
using two 1k resistors and two 0.1 uf caps after the 1N34.

> He measured a ratio of 366 between common mode and differential mode
> with a resistor. Why is yours so differnet, or is it?

As you probably know, that ratio could be almost anything.
Mine was approximately 60:1 It is only approximate because
the pickup coil is introducing a small amount of choking
impedance. That choking impedance is negligible compared
to the impedance of my choke and that is what I was most
interested in. This experiment is easy to duplicate. PU
is the pickup coil whose voltage drives a 11k resistor
and is rectified by a 1N34 diode.

XMTR---tuner---PU---choke-X---ladder-line---dipole

> What are you actually measuring?
Since my pickup coil introduces an impedance, I wouldn't call

it measuring. I am *detecting* common-mode currents. I've got a
11k resistor across a 20T FT-114-61. The fact remains that I
detect minimum common-mode current when the choke sees a
differential Z0-match at point 'X' above and the common-mode
current rises on both sides of the Z0-match. This agrees with
my original statement.

As W5DXP has pointed out, the parallel folded dipole approach won't
work very well because of the low feedpoint Z of a one-wavelength-long
folded dipole.

> I am going this route because I have had poor results with

Yup. And a typical 4:1 balun is designed for much higher impedances.

> I figure than 300 ohm twinlead matched a folded dipole nicely, and then
> transforms to 75 ohms on the other side of the balun, easily matched by my tuner.

That'll work OK on one band, IF the reactance is low enough.

> Coax is out, since I have been persuaded in my reading that a single random length
> of 75-ohm coax seldem, if ever, really matches several parallel dipoles, nor does
> it match the 40 wires on 15 that well.

It's all a matter of what you consider an acceptable match and how
much pruning you're willing to do. The parallel-inverted V setup works
best if you can separate the wires, maypole fashion.

> Plus, I want to use parallel feedline so
> that I can feed *both* wires against ground as a vertical for 80. Can't do that
> with coax, can you?

I've done it with coax. Used an 80/40 trap inverted V on 160 that way.
Short coax inner and outer conductors and work the whole mess against
ground.

I guess I don't see what you are trying to prove.

(Almost) everyone knows that common mode currents do not have to
track, and most often do not track, what occurs differentially in the
feedline.

Examples abound.

One is the wive's tale about tuners and baluns. Moving a balun from
the output to input of a floating ground network, which does nothing
to improve effectiveness of the balun.

Another very common example is with a dipole, where the feedline and
antenna are matched. The ratio of common mode currents and voltages
vary all over the place with no relationship to the constant
relationship of current and voltage inside the cable.

A third is with a feeder with standing waves, where the velocity
factor is different inside the line and outside, and where the line
impedance is much different in common mode than in differential mode.

Since we all know (or we all should know) that making differential
mode impedance low does not guarantee common mode impedance is low,
what is the point of measuring two specific things in a unquantified

and unknown test situation?

Certainly we should have some idea what we are measuring when trying to learn how the real world works, if we don't already know that.

Source record: 156231

More likely the gamma matching section is set incorrectly. Try placing the antenna atop a stepladder so that it is pointed skyward and the rear reflector is at least 6 feet (one wavelength) above the ground. Then insert the VSWR bridge at the antenna and readjust the gamma match for lowest VSWR.

If you are now able to get the VSWR adjusted to 1.5 or less, any remaining problem is not in the antenna but possibly a bad connection in the feedline. If you cannot get it down to 1.5 maximum it is likely that the antenna dimensions are in fact too long as Cecil suggests.

John Miller, N4VU wrote:
"If you have a 200 000 amp lightning surge flowing through 0.2 ohms impedance between grounds 16 feet apart, the voltage drop is 40 thousand volts."

Yes. This shows how small an impedance can produce a disasterous voltage drop when a lightning stroke is involved.

My first thought was that measured resistance between ground rods might be about 20 ohms resistance. This just happened to be the value I was told to use in a similar problem assignment in an early EE course back in the 1940`s. I remembered it and thought it might be appropriate but everybody knows soil conductivity varies widely.

The ground rods of the questioner were 16 feet apart and connected above ground with a conductor.

The inductance of a straight round wire at high frequencies decreases with wire diameter and increases with length. See the graph on page 48 of Terman`s 1943 Radio Engineers` Handbook.

Even a large diameter cable 16 feet long may have 4 microhenries of inductance. The frequency at which 4 microhenries offers 20 ohms impedance calculates to be 796 kHz. So I don`t believe we erred very far by picking the 20-ohm value out of thin air.

Sounds kinda like the elements are a bit long for one thing. Unless
you actually designed the antenna to be tuned that low in the band. If
that was the case, I'm wondering why the vertical polarization.
Usually an antenna tuned that low would be used for ssb/cw and be
horizontal mounted. I'd stick it on a short 5-6 ft mast that you can
stand on the ground and mount in it's normal position. Make sure the
mounting is the same as up on the roof as regard to the position of
the mast to the reflector or elements. I don't know if you end mounted
it like a small beam, or mounted it with the center of the boom at the
mast like a large beam. That could make a small difference I bet.
On 2m, 5-6 ft should still be high enough off the ground to get fairly
normal tuning as compared to its regular mast. You know it's tuned
low, so you need to adjust the gamma match to be a tad shorter, or
maybe adjust the cap. If it still tunes low, you may need to tweak the
elements themselves. Did you use the exact tubing or rod sizes as in
the plans you used? This is very critical on a vhf/uhf beam. If it's
exactly as per the plans, it should be able to tune just by adjusting
the match. I would only attempt to trim the elements if you know for
sure that you cut it a bit long, or used a different size tubing than
the plans called for. It's hard to add it back, if you cut too much.
Also you would want to trim each element equally and in very small
amounts. I'd try the match first. MK

482. Re: Grounding 2 stations

A single-point grounding system is best achieved using a
small "window" (copper plate) where the various protectors
share a common grounding point.

> lucky placement?

It all depends on what you want to work and what bands. A 66 ft
vertical would be great for 80m dx with a few radials strung out. But
it's really too tall for most of the other bands. It could be used as
a 1/2 wl vertical on 40m, but would need matching. It's probably
almost a 5/8wl or so on 30m, and could ne used with a loading coil.
Most of the higher bands it would be a dud because it's too tall.

You would only need loading for 160m with a 66 ft vertical. And yes, a
top loading wire ala INV-L would be the way to go rather than using a
coil.

probably not on 20m if the horizontal 20m dipole was fairly high up.
On 40m, a 1/2 vertical could could be an improvement over a low dipole
for dx. But don't forget ground losses. Just because it's a 1/2 wave
and complete in itself, doesn't mean ground losses can't get you. But
over a few radials, yep, a 1/2 vertical on 40m could be a pretty mean
antenna for dx. But for regional stuff a horizontal dipole would be
much better. Use both if possible. A 40m dipole at 60 ft won't be a
total slouch to dx itself.

Myself, I'd get horizontal dipoles/inv vees up at 60 ft, being you
have the support. If it were me, I'd run parallel dipoles for 80m,40m,
and 20m, on one coax feed, or use a single 80m dipole and ladder line
and a tuner. I prefer the parallel coax fed antennas because no tuner
is needed, and the patterns are fairly dipole like on each resonant
band. With that antenna at 60 ft you will do fine. Heck, I've been
working 20m with the same type 80/40/20 antenna at only 40 ft and do
quite well on 20m. I work SSTV with only 40 watts, and am usually
closed circuit to those in the US. And also do well to far dx. I've
worked a boatload of dx stations on sstv and most get pretty decent
pix from me. I'd try the verticals as secondary antennas aimed for dx.
Mainly the lower bands. There are many options...A 30 m dipole fed
with ladder line and a tuner is good for 30-10 with a good pattern on
all those upper bands. A cb antenna is good for 10m. An inv L or T is
good for 160m. A dipole on 160m is good for close in stuff "out to 500
miles"?? but not for dx unless it real high up. MK

At my workplace they use McAfee. It is constantly getting in the way and
they had a big problem a while ago with some virus or other getting through.

At home I've got Norton and it is never in the way and nothing has gotten
through as far as I know.

There seems to be a big difference IMHO.

Sorry to drift off topic.

Height is your answer. In an excellent book by the late Bill Orr, W6SAI, he describes an elevated vertical with four radials (multi-band, using three radiators and four radials made of antenna rotator cable). By raising the base of the antenna off the ground (I've used about 10-12 feet elevation), you reduce the need for more than four radials. This is supported by John, ON4UN, in his excellent book on low band DXing.

Good luck and good DXing...

Bill, W4WNT

Dave- and all-
I got this warning, and stopped everything, went off line, started the (Norton) virus checker, set to "all files".
THen- there was published a note that this was NOT a virus, but someones Idea of a joke, written in JAVA, to post the warning- thats all. Norton did not find anything, and, a check of the files showed no such virus.- Lots of fear and time wasted.

Personally, If I caught the guy who wrote this 'joke', I would do BAD things to him. I am not a violent person, but he might sing soprano after I had my way. I have a social advantage over him/her, in that my parents were married when I was concieved, and his/her parents were not.

About the McAfee, vs Norton- I have taken McAfee off all our computers, and archived them. They have caused me more problems than they have avoided.

Rabbit Music wrote:
"...or can I just get a fairly inexpensive one (as long as it runs at the correct amps)?

Sure. I look for bargains that I expect to be useful in the future. My junk collection is really big. Such was the 12 VDC power supply I bought for $10 or $15. I think I paid $0.25 / lb.
It runs continuously and is cool. It is a Lambda LXS-D-12-R. In: 105-132 V, 57-63 Hz, or In: 47-53 Hz. Out: 12 V d-c, 16 A with 60 Hz input or 14 A out with 50 Hz input.

I replaced a similar supply which was submerged during the great June flood here. It had run flawlessly for years and is repairable. The instant fix was a fast swap with one that stayed dry. Someday I may get around to repairing the original.

Surplus is out there that is good and cheap. You need to make it to the right place at the right time if you want to use your time chasing bargains.

Best regards, Richard Harrison, KB5WZI

that message was bogus. there was no virus, it was simply some embedded
script that put up a dialog box that said you had a virus.

An argumentum ad populum? You have gone from saying they are
"unrelated" to saying they "most often do not track". What if,
in certain antenna configurations, they most often do track?

> One is the wive's tale about tuners and baluns. Moving a balun from
> the output to input of a floating ground network, which does nothing
> to improve effectiveness of the balun.

"Nothing"? There you go again with another absolute. From my testing,
it seems to me that moving the balun to the input of the tuner, while
not having an effect on some of the common-mode current, might actually
keep the balun from *causing* common-mode currents. I will run
that experiment and report back.

> Since we all know (or we all should know) that making differential

> what is the point of measuring two specific things in a unquantified
> and unknown test situation?

I have shown that there is a relationship between the differential

impedance and the common-mode currents in my antenna system which is
a very common configuration. You said they are "unrelated". The point
is expanding knowledge. I still have things to learn. How about you?

490. Hustler 5BVT instructions

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-10 22:48:39 UTC
From: kb0haespam.stimks@arrl.net
Message-ID: <3bc4cf56.2257193@news>
Source record: 156242

Hi Folks. I have a Hustler 5BVT that I bought second hand from a local ham. All of the parts appear to be there, but he didn't get the instructions. Can anyone copy these for me, or is there a source online for them? Mainly, I need the measurements for mounting the antenna on a short (10 feet) mast. At my location. this is as high as I can safely mount the antenna due to space and other considerations.

Thanks

Cul8r

Message-ID: <3bc4d43f.182438748@news.netis.com>
Source record: 156244

I'm looking for the very BEST, highest gain antenna I can find for a handheld, for the 2M and 440-MHz bands (if it has 220 MHz as well, so much the better, but that's not important).

An SMA connector would be ideal but I can live with a BNC (I have a BNC to SMA adapter).

This is to be used with the Kenwood TH-F6A, whose supplied antenna is OK but like all rubber duckies, it is limited in capability.

Thanks...

A *wooden* stepladder -- if you can find one now-a-days.

Elsewise, use a temporary, longish mast and clamp it to the top
of the stepladder with the antenna as far out and away from the
aluminium stepladder as possible -- using a counter weight of some
sort on the _other_ end of the (now horizontal) mast.

Hello Tom,

Agreed - if the antenna/transmission line system isn't balanced to begin with, changing the tuner setup won't help.

I won't reopen the whole voltage/current/bead/toroid balun can of worms. In fact, I really wasn't thinking much about balance at all when I wrote the above. Sorry if I was unclear - thanks for the comment.

The main concern I have about the isssue is the use of the typical "bifilar wires on a toroid" balun at impedances far removed from the design impedance. Often there is considerable reactance involved, too, and the results aren't pretty.

In Will's case, suppose he puts up an inverted V of about 70 feet of wire and feeds it with about 80 feet of "450 ohm" line with VF of 0.8 (about 100 electrical feet). In other words, about a half wave of wire on 40 fed with about 3/4 wave of feedline. The "shack end" impedance of such a setup may be such that the "4:1" balun in his tuner is trying to deal with impedances of several thousand ohms resistive part, and maybe sizable reactance as well, none of which it was designed to handle. End result is lots of loss and poor results. A coax-fed trap or parallel dipole will probably be a much better performer, even if the tuner (less balun) is used to deal with moderate SWR (3-4:1) on the coax.

Speaking of traps, I remember that just before Dayton you had some info on losses in various types of traps and that the "coax on a PVC pipe" ones didn't look so good. It would be great to see that info, either here or on the pages of QST.

Yes, I don't disagree one bit. My point was that even if we suppose a case
two orders of magnitude better, we're still dealing with Big Voltages!

If two things are never in a fixed relationship, they are unrelated so
far as the meaning of my post.

You feel they track, the rest of the world pretty much knows they
don't. Common mode is an entirely different thing than differential
mode. It is a different circuit, with different impedances and actions
of one are unrelated to the other.

Now you might find a special case where they are the same, but that is
either a planned special case or pure dumb luck.

Come on now. Draw it out on paper and look at the common mode voltages
or current through the balun. They can't possibly change with a
floating network, despite a large change in differential impedance.

For example, look at a T. Then move on to any other floating network
with a current balun.

Without knowing or understanding what you are measuring, you haven't done anything but waste time.

>impedance and the common-mode currents in my antenna system which is
>a very common configuration. You said they are "unrelated". The point
>is expanding knowledge. I still have things to learn. How about you?

Not about this topic. It really isn't that complex.

My first experiments and lessons were in 1970 or so, when I built a reversible Beverage that sorted common mode from diferential mode currents quite well.Telephone lines can use that effect, and virtually all transmission lines do.

Anyway have fun. You obviously are just looking for an argument, and I have no time to waste.

All it is is a small vertical. It will have the same problems as any
other small vertical with efficiency and bandwidth.

Results will depend on how good the loading inductor is, and the
ground system. You can bet it won't be close to a good full size
vertical, not by a long shot.

Nah, you just make the first quarter turn or so either wider (add a "plate") and/or closer to the reflector. Standard practice in many of the plans that I have seen. No, I haven't built one yet - so Guilty of talking thru my hat (so to speak). I hope this helps.

You're certainly correct about the reversal of sense (LHCP/RHCP).

YOu may want to rethink the antenna type for 2 meters. There is no easy
way to reverse the sense of a helical and often it is needed for the
sats. Also the 140 ohm or so impedance is often difficult to match to
50 ohm coax. The crossed yagis are more managable.

|balance.

Tom as you well know, there is no love lost between Rich Measures and me. That said, I must agree that his approach of a balanced tuner with a balun on the input is valid.

Consider the balanced tuner to be nothing more than a series section of balanced transmission line of variable length and impedance or a shunt line of variable length and position. Would you argue that a balun on the input of this line is ineffective? If so, then we best throw away our baluns.

Be careful of the words you use. I think they *can* track and the
rest of the world pretty much thinks they *cannot* track.

> Now you might find a special case where they are the same, but that is
> either a planned special case or pure dumb luck.

My antenna is not a special case at all and yet they track. With my
antenna system, common-mode currents are minimum for a differential
Z0-match and increase to each side of the Z0-match.

> Come on now. Draw it out on paper and look at the common mode voltages
> or current through the balun. They can't possibly change with a
> floating network, despite a large change in differential impedance.

We have all waded through that exercise. But we assumed the common-
mode current was unrelated to the differential mode current. Thus,
we begged the question. If a misapplied balun can introduce additional
common mode current, then that model is not sophisticated enough.

> For example, look at a T. Then move on to any other floating network
> with a current balun.

I'm going to do better than look at it. I'm going to measure it.

> Anyway have fun. You obviously are just looking for an argument, and I
> have no time to waste.
You haven't addressed the question, Tom. What if a misapplied balun can

cause additional common-mode currents? I'll bet you didn't allow for
that in your mental model.

OK, that clears one issue right up. I had been trying to apply my limited understanding of antenna circuits to info gathered from a number of print sources, and combine/synthesize something that was not directly or explicitly treated in any of the books I have been reading ('91 ARRL Antenna book, various ARRL compendia, various W1FB pubs, Joe Carr Practical Antenna HB, and some 50's-60's ARRL HBs). I *am* glad you commented, since I would have been annoyed if I had done all the work and the system failed utterly to work. Annoyed, and further frustrated because I would have taken weeks to figure out that I had a basic design flaw rather than parts or installation problems.

How else can I feed several folded dipoles? Will it solve the problem if I run two folded-dipoles, one for 40/15, the other for 20 "parallel" at right angles to each other (in a '+')? Can I use one feedline that way? I suppose I can just use one feedline for each antenna if nothing else will work. Is the issue *parallel* folded-dipoles, or is it just *multiple* folded-dipoles with a single feedline? Of course single 100' V and ladderline would make all this moot and simplify things, but my little tuner just can't handle the 20:1--plus SWRs it is likely to see into one of those. . .

I think what Tom is saying is that given a fixed common mode current,

the balun will see that common mode current whether it is located on
the tuner output or on the tuner input. That's true if the common mode
current is a constant. But if the balun on the output of the tuner is
the *cause* of the common mode currents, seems that moving the balun
to the input would change the common mode currents. I'm going to run
that experiment early next week.

In my antenna system, the common mode currents are at a minimum when
the system is Z0-matched. Consider a 50 ohm unbalanced to 50 ohm
balanced junction. There's no reflections. Consider a 50 ohm unbalanced
to 100 ohm balanced junction. There are reflections. Do those reflections
partially contribute to common mode current?

The issue is that any folded dipole that is a multiple of full wavelengths
is close to a dead short. A 40m folded dipole is one full wavelength on
or around 20m.

> Of
> course single 100' V and ladderline would make all this moot and simplify things, but
> my little tuner just can't handle the 20:1--plus SWRs it is likely to see into one of
> those. . .

You can solve the problem the way I have. On any band, there is a length
of feedline that will allow your tuner to work with your antenna. For instance,
you could put up a 66ft 40m dipole and feed it with a multiple of 1/2WL of
feedline on 40m. It will work just fine on 20m if you feed it with an odd
multiple of 1/4WL of feedline. Thus adding or subtracting about 16ft of
feedline to/from your 40m setup would work on 20m. Some other length would
work for 15m and 10m. You might get lucky and only need two lengths for all
four bands.

For virtually any ladder-line fed dipole that is 1/2WL at the lowest frequency
of interest, there is a length of feedline that will work with virtually any
antenna tuner. There is usually a length of feedline that will give an SWR
less than 2:1 without an antenna tuner.

Will, just a very basic observation: a folded dipole will not perform any
better or any differently than a simple wire dipole of the same length and
same height above ground. The sole merit of the folded dipole is that its
driving point impedance is multiplied by a factor of 4 which means that it
is a fair match for 300-ohm twinlead.

If you could set folded dipoles aside and concentrate on the main problem
of multi-band operation, I think that you will begin to appreciate the
merits of wire antennas fed with tuned lines and/or multiple wire dipoles
fed in parallel with coax. The only other notion would be separate dipoles
for each band fed with individual feedlines.

I do not know what impressions you have gained from your reading about the
folded dipole, but trust me, it has no merit over a wire in the same
location. The only difference is in the driving-point impedance.

Not entirely. It infects on opening the message, not on opening an attachment. Evidently it is mild as viruses go,if that's what it is. First time I got it, it changed my dialup configuration by altering my password and username plus locked up the machine. After power down and reboot I had to rewrite my logon data in Windows Dialup Networking to get back online. I could find no other problem. The latest Norton didn't catch it nor could it find it with a full system scan.

Next two times it came in in newsgroup messages it just locked the computer to where the only way I could get the message off the screen or do anything at all was to power down the computer without closing out any programs or windows and reboot. Ctrl/alt/del wouldn't reboot and I could not cancel the message window. I now don't automatically open all messages on a newsgroup. The idiot posts them to other NGs also. Looks like someone has found another way to be a pain in the posterior. What some people have to do for their fun.

Indeed! I have in mind the construction of just such a device. I have several construction articles for link-coupled balanced tuners. Looks like a *very* easy project, just two variable C's
and three pieces of coil stock, some clips, jumpers, etc. I should be able to cobble one together
that is sturdy and offers a wide range for ?100W in an afternoon, for less than $50, using *new*
parts. I think it's time to stop putting off that project. . .

I had a look at the AG6K circuit (http://www.vcnet.com/measures/), and that is an interesting,
promising circuit, with well-written and very thorough docs. Due to mechanical and budgetary
constraints, I am going with the link circuit for now. So many projects, so little time/space/money, ah.

THanks for your patient reply, though I still don't understand two points. First, you report that the feedpoint Z of a resonant folded dipole operated on its 2nd harmonic will be =5 ohms. So (it isn't my intention to use you as a calculator, really!), what would the FP Z be at its 3rd harmonic? Second, though I get what you say about 1/2-wave FDs behaving as dead shorts on their even harmonics (at least those freqs. where the antenna is a full wavelength or integral multiple), I don't understand, as yet, why this should preclude the operation of the system I have been describing. Presumably (uh-oh. . .), as with single-wire multiple dipoles (fed via one feedline), the RF "knows" the proper impedence path when it sees it, and thus a 20M signal will select the 20M antenna, a 10M signal will choose the 10M antenna, and so on. This has been my understanding of how parallel dipoles (the regular type) work. I have a nagging sense that I am ignorant of something (probably pretty fundamental, alas) here, and hope you will dispel that for me.

Nearly, but they will differ in distance and/or impedance to the
actual ground.

> If not, the third
> wire grounding your equipment should reach the service entrance ground
> via the "ground window" to which it is connected in passing.

This is unsafe and a violation of code as well as creating a "ground
loop". The NEC addresses this need and should be followed if
"nearly" is not good enough.

> The antenna ground on your radio should pass through and be connected to
> the same "ground window".

Yup.

Dear Yuri,

Thanks for your reaction.
But I do not want to design a yagi, I want to model/design a quad as
mentioned.
I know about all pro's and cons on the subject, but as mentioned I do not
want to start a discussion about this. I just want to build it and compare
it over some significant time.
Sorry for being so short on this matter.

Peter K1PO asked Mark about inverters:

Costco/PriceClub sells an inverter for Cdn$60 (should be ~US$40). Superex "300W" - I think I recall that it was claimed as being "600W peak" (but I won't swear to that). Perhaps someone can confirm/deny. It is 7"x4"x2" roughly. It has a fan. I got one for light duty use. (Once the 4" LCD TVs get a bit cheaper, I will put a VCR & TV into a portable kit so that the munchkin can watch his Disney movies all day while we drive on long trips.)

The suggestion of using a PC UPS reminds me of a story (uh oh...).

Many years ago, at the start of the car stereo wars, my buddy got tired of the silly baseball hat wearing lunatics driving $400 cars with $800 stereos. So one fine Saturday morning, he installs his entire home stereo (less turntable) into the back of his VW van. 400 (real) watts RMS, a couple of Radio Shack 'Mach 1' speakers (with 15" woofers) and a 2nd pair of speakers almost as big as the first. The whole mess was powered by a borrowed computer UPS. That day (well - for about 10 minutes anyway), he was king of the lunatics.

Don't overlook the 800 to 900 ohm resistor in series with the folded
dipole loop. It's a terminated folded dipole.

The tuner is supposed to go between the coax and the long wire. That's what
a tuner is for.

I am one who has used paralleled dipoles for years, with a variety of
tuners both external to to the transciever or amplifier, and internal
auto tuners built into transcievers (several varieties). I can recommend
them since they have been fully satisfactory. Just use good quality coax
that is rated well above whatever power level you will run.

Well, coax won't necessarily protect your rig from picking up EMI from the PC.
Been there; tried that. Move the PC. Or move the rig (it is *tiny*.) Or see if
you can add some filtering.

Will White wrote:
"Not that I am wedded to the idea of a FD----."

Crazy George answered my question of how a FD TV antenna works. It seems a fundamental resonance frequency is picked which will have destructive harmonics which fall outside any TV channel of interest.

Ham bands tend to be harmonically related.There may be a way to parallel FD antennas when one is resonant on the second harmonic of the other.

Arnold B. Bailey in "TV and Other Receiving Antennas" gives feedpoint impedances for folded dipoles of various end-to-end lengths:
1/4-wave = >1000 ohms
1/2-wave = 300 ohms
3/4-wave = ~ 1000 ohms
one-wave = very low, Cecil est: 5 ohms
1 1/4-wave = high
1 1/2-wave = low
Etc.

Suppose a 14 MHz FD is fed with 300-ohm twinlead. Suppose this twinlead is extended beyond the 14-MHz FD by another 1/4-wave, or 3/4-wave of twinlead at 14 MHz to a 7 MHz FD.

At 14 MHz, the 14 MHz FD is a 300-ohm load on the twinlead which feeds it. The 7 MHz FD has an impedance which is very low, almost a short, because this 7 MHz antenna is one wavelength at 14 MHz.
The short-circuit presented to the 1/4-wave extension is transformed to an open-circuit across the 14 MHz dipole. The 14 MHz FD should work well.

At 7 MHz, the 14 MHz FD has an impedance exceeding 1000 ohms because it is a 1/4-wave antenna at 7MHz. This is just a >1000-ohm shunt across the twinlead to the 7 MHz antenna. The 7 MHz FD should work well. The 14 MHz FD may impose some reactance across the transmission line. This can be tuned out at the transmitter end effectively because the twinlead is not particularly lossy.

There are sure to be other games to be played with line matching sections to connect one antenna while disconnecting another. This just popped into my head and seems to me that it might work. I believe there are such methods available which can be used to avoid some switching.

Best regards, Richard Harrison, KB5WZI

The raw antiresonant feedpoint resistance of about 5 ohms would be
in series with 800 ohms. That should definitely put a notch in the
free space gain.

> --Peter K1PO

Actually I haven't really. I'm using an old heathkit model that is
about as old as dirt. It's only about 175w cont. and maybe 240w peak.
You can get ones much bigger than that. I see them sold at many
places. Radio shack, wal mart, etc, etc. You would need a big one to
run all that stuff in a car. I'd use a 12v rig on it's own in that
case. Also you would likely have trouble using a lighter socket unless
it's one of these heavy duty hi current versions. I always prefer to
run wire to the battery. I also am going to do much the same if I ever
find a laptop. I want to rig it up like a cop car with the laptop up
on a pedestal, and the 706 faceplate on it's own pedestal next to it.
if I ever get that rigged up, I want to add a GPS to it which would be
run through the puter for a better display and maps. In general I
don't really like running HF rigs of inverters. I've tried it with a
TS 520 and it works, but the plate voltage can drop a good amount
under load, and the performance wasn't as good as when plugged into a
normal 117v socket. I don't know what kind of rig you have in mind. I
much prefer a 12v radio in the car. MK

Don't put up with that nonsense. Crashing computers is just so 1900's and is really starting to go out of fashion.

Go to URL = http://nonags.com/nonags/

Scroll down to:
"Internet:
* FTP Clients"

There are about 19 FTP Clients to choose from. I happened to choose 'Max-FTP' because it was rated 6/6 and I thought it worked okay. There are plenty to choose from - for Win-ME look for "Mill". Since the P in FTP is for Protocol, they *should* all be compatible for your FTP'ing needs.

By the way, Nonags.com is chock-a-block full of high quality Freeware. "Nonags" refers to no hassles about donations or registration fees (not shareware, but actual FREEware). If you haven't been there before, try not to stay up all night...

Good luck.

Maybe so, but I've never had any trouble with regular chargers. I used a small 3 amp trickle charger for years and it will do the job. But I now use a 12 amp automatic charger with it usually on low which is about 2-4 amps. I like having the higher capacity charger when I run CW, etc. I can hammer full power, and usually get back up to full charge while I'm on receive,even on low. It can jump a car at 75 amps. Even 12 amps is a fairly slow charge for a car battery compared to the rates it charges at in a car. I used to sometimes forget and kind of overcharge with the trickle charger. I never have to worry about that now. I use normal deep cycles and car batteries both. I only need one for a 100w rig here at home with the charger. Prefer the deep cycle for radio use if I'm not on a continuous charge. "Out in the boonies" I use anderson connectors on everything. They are about like the ones you mention. I like having multi batteries out in the sticks, but only use one at a time with the 706 alone. If I get a solid state amp for it I'll need to use two. "500w range". I used to run a 730, and it was always on batteries also. But it pooped, and I replaced it with the 706. I'd still like to find the part to fix the 730. It's still good except for one lousy part on the display board. I'll find one some day in a junker 730... MK

Any one know where I might pick up a ceramic feed thru insulator that was in use years ago when paraell house wiring was in style.They were abt six inches long and were used to run say a #14 wire thru a beam or rafter. Thanks

Hi Cecil,

I use WS_FTP from Ipswitch, freeware. Most programmers use it or
PrettyFTP. I also publish through a web page editor called Visual
Page which contains FTP functionality. There are no unreasonable
mappings into QSL.NET nor arcane protocols. It may be slow however
and your system crashed through an unexpected time-out? If the app
crashed, it was a timeout. If the system crashed, you need WS_FTP.

I use IE and no problems so far. It and Norton didn't complain about any
virus over the last few weeks.
>
Well, It did one, but it wasn't from this group.

As to Netscape. I did have both IE 5.5 and Netscape . Then upgraded to
Netscape 6.0. I only left it on the computer for a couple of days. It
workd well, but they have so much on the title bar that the view window in
the broswer was way samller on my 19 inch monitor than it is on this 17 when
using IE.

As I say, It worked well, but I didn't like the looks, or layout. I had
also installed it (Netscape 6) on my wifes machine and 15 minutes later she
came in and asked for the old browser back.

There may be other places with feed throughs, but I do know that Surplus Sales of Nebraska has very large, even huge, ceramic feed through insulators. They have a web site.

Source record: 156195

Today I decided to make a double bazooka antenna for 3.7mhz, testing the finished item I used my MFJ-259 and found the antenna resonates on 2.4 mhz.

The only difference was that I used RG58 CellFoam coax, the makers (RF Industries an Australian Rf Specialist) specs say that is has a 76% VF, (and now I doubt this) which I
used in the calculation.

My question is that as I understand it I can use my MFJ analyser to find out the true VF of the coax, I have a small piece left over.
When I test the coax do I terminate the end of the coax with a 50 ohm non inductive resistor, shorted or open ended?

WS_FTP is what I downloaded from QSL.NET. My computer said WS_FTP

was performing illegal operations and would be shut down. What now?

>
You can still establish a completely seperate
common point grounding
window for each station (for lightning). The ground rods can
be bonded together to meet electrical safety codes; but
each station has its own power, coax, telco, protections
sharing a common ground plate.

547. Common mode currents, RF feedback, and RF transceiver grounds

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-13 15:03:08 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0110130703.19d79fee@posting.google.com>
Source record: 156200

1. Can RF feedback or RF-in-the-shack occur if there is ZERO common mode current in the transmission line?
2. Is there any reason one would need an RF transceiver ground, 1/4 wavelength counterpoise wires (as a substitute for the former), or an artificial ground tuning devices if there is ZERO common mode current in the transmission line?
3. Why do people say that balanced antennas like dipoles don't require RF transceiver grounds, 1/4 wavelength counterpoise wires, or artificial ground devices even though chapter 26 of _The ARRL Antenna Book_ shows that even supposedly balanced antenna systems can be unbalanced and can thus have common mode currents?
4. What does RF transceiver grounding accomplish in this picture? It seems to me that it's easier to minimize common mode currents with RF chokes, baluns (for dipoles), and a better RF ground plane (for monopoles) than to add RF transceiver grounding.

There's just one problem: It's cumbersome. You can't adjust the tuner
from the control point unless you have a remote control tuner.

Mark et al:

Yeah thanks, now that you have mentioned it, and I have given it some thought...

I do have a "500" APC UPS in the house for my desktop computer, but it's not really a solution for wilderness camping out of an SUV. It too has gotta be recharged.

I believe that instead of an inverter... what I really need to do is...

I need to buy myself one of those new mobile 12VDC HF rigs. Say like the IC706 or FT-100. That's a great idea, I'll ask "Mary" if I can get an early Christmas present, heh, heh...

But... when SUV travelling... what about the laptop which I use for PSK-31, and other digital modes at home, etc...? I run my Sony VAIO laptop in that application most of the time. The laptop runs off it's own internal battery(s) for a few hours, and that's OK when at home since I can recharge from the home AC outlets, but then... what's the best way to recharge the laptop's batteries if one is not near an AC outlet, i.e. when travelling or wilderness camping by car?

I guess a small inverter plugged into the cigarette lighter adaptor coupled with the laptop's 110 VAC portable charger is one way to go. Sony apparently does not have a "direct to 12VDC adaptor" for it's laptops. I wonder if the laptop accessory manufacturers make such devices.

confusion with references to common mode, balanced and 'supposedly
balanced'. You are imposing relationships that are not real.

I wish it was more clear what you have against grounding. you seem to be
as obsessed on this as Rich Measures is on parasitics. You should stop-
take a deep breath, and THINK about the real relationships and
'cause-and-effect' here before proceding.

I wrote:
"---the third wire grounding your equipment should reach the service entrance via the "ground window" to which it is connected in passing."

Sylvan Butler wrote:
"This is unsafe and a violation of the code as well as creating a ground loop."

I don`t have a copy of the NEC but the code usually makes sense. Ground wires can be bare and often are. I don`t think this is a violation. A bare wire can make multiple contacts to "ground" in many cases.

An equipment ground wire making contact with other grounded points enroute to the service entrance ground does not seem hazardous to me when all of these ground points are well connected to the service entrance ground.

The purpose in connecting all a radiio`s conductors either directly or through an arrester to a ground window is to ensure there is no dangerous potential difference at the ground window point.

It is advisable to ground the antenna coax shield to the base ground of an antenna supporting tower and then ground it again at the station entrance. Ideally, the station entrance coincides with the electrical service entrance and with the ground window.

A ground loop is a common impedance through which a current from one source is coupled to another circuit because the first source and the second circuit share the common impedance.

Separate ground wires to a single point are intended to avoid a common impedance through which current from one circuit is imposed on another.

For example, you should not make the antenna coax connection to your radio the first antenna system ground connection if the radio ground is the "green wire". The green wire becomes a shared impedance for the power and antenna systems. The green wire is coupled to the other power wires by shared electric and magnetic fields. Lightning can be coupled between the antenna and power systems through the green wire with this sort of grounding.

Ground the coax where it enters the station at the same point where power and wired communications systems are grounded directly and through arresters.

Best regards, Richard Harrison, KB5WZI

Sounds like a plan.

>My question is how can I interface the long wire and the coax?

Get a remote tuner. Another poster has suggested the SGC units, which have a good reputation. There are other tuners that can be remote controlled. The tuner for a long wire belongs at the end of the wire, near a short ground connection.

> I have seen a
>product from Palomar called a magnetic balun that is supposed to do this.

For receiving, maybe. For transmitting, forget it.

Due to the proximity of the computers, you may find that the
unwanted signals will be much stronger when using the
building as a tuned antenna.

Zack,

I assume your outdoor layout (property) precludes a dipole or other balanced antenna. OK, so does mine. Did you consider an end fed Zeppelin antenna? Basically, a giant j-pole. Mine is 125ft of wire to ONE conductor of a 45ft piece of 450 ohm ladder (window) line. Use these figures, they work for sure. Feed both conductors of the window line with a common (L) antenna tuner with balanced line output (IN the shack.) If you can get it up high enough, it will work all bands sans ground (counterpoise.) A wire or two may have to be added for 160m. The MOST bang for the buck on a end-fed antenna without going the remote autotuner route, and no counterpoise. It's a cloud warmer down low, but if you can get 'er up in the 30-35ft range, should yield a nice antenna, without the RF problems of the typical longwire. I DO NOT KNOW if this antenna can be shortened, or how to calculate. There is plenty of data on this antenna on the web, just search around. Run the window line only directly perpendicular to any metal (such as siding,) and keep it as high and in the clear as possible. Mine makes a giant curve from a "center insulator" directly into the attic via an eave vent, is suspended from the attic roof peak and drops directly down into the ceiling of the second floor shack to the tuner. I used banana plugs for quick disconnect and re-connect to ground for storms. Good luck.

Joe

Hi Cecil,

This is indeed odd of the app. I've been using this package for 5 or
6 years and have installed many 100's of pages. However you include
WindowsME in your OS list (I'm not sure that is your OS, but along
with LINUX on the other box, I use this) and that for me crashes at
least once a day. My version is 5.08 by the way.

I've quipped to my buddies that WinMe has some of the best recovery
tools that I have ever found in a Windows product - I should know, I
use them frequently. If you are also saddled with WinME, go to the
Help screen and try doing a system recovery. Pick a date that
precedes the last installation of software you performed (which is not
to include WS_FTP by the way, it is a victim not the problem -
however, the recovery may force a new install).

WinME will allow you to recover to today's system settings if this
experiment (or others like it) serve no purpose, or fail even more so.
As I said, I've used this tool frequently and (what is odd for a
Windows product) I have never had to re-install Windows even in the
face of brutal crashes.

How did you perform your page maintenance in the past?

>1. Can RF feedback or RF-in-the-shack occur if there is ZERO common
>mode current in the transmission line?

As you pose the question, no. However, this is only one mechanism of what you characterize as feedback (a term that is more properly applied to amplifiers). That is, it is a problem due to conduction (the coax shield supporting the Common Mode current). The same problem could as easily be supported through radiation (hard to imagine RF in a convective argument tho'). The conduction based intrusion of RF is more pernicious (a stronger coupling back into the shack). If RF were to arrive on the basis of radiation, it would be reasonable to expect that some evidence would also be found in the shield currents (again weaker than by direct conduction) such that ZERO would be quite suspicious.

>2. Is there any reason one would need an RF transceiver ground, 1/4
>wavelength counterpoise wires (as a substitute for the former), or an
>artificial ground tuning devices if there is ZERO common mode current
>in the transmission line?

One must first examine WHY there are ZERO CM currents and we would find that this could be evidence of good grounding, 1/4 wave counterpoise wires, etc. They are not necessary as a very poor installation could as easily display a lack of CM currents.

This is to say, if you have no "apparent" problem, this is not the basis for taking off your parachute.

>3. Why do people say that balanced antennas like dipoles don't
>require RF transceiver grounds, 1/4 wavelength counterpoise wires, or
>artificial ground devices even though chapter 26 of _The ARRL Antenna
>Book_ shows that even supposedly balanced antenna systems can be
>unbalanced and can thus have common mode currents?

You are drawing a fine line in this terming of RF transceiver grounds. This implies a distinction where formerly there was none. Yes antennas sometimes have a ground connection, and sometimes the rig has a ground connection, and sometimes they both have a ground connection. This is not to say they are different grounds even if they are physically separated (the whole point of bonding grounds for safety). I will explain further, below.

>4. What does RF transceiver grounding accomplish in this picture? It
>seems to me that it's easier to minimize common mode currents with RF

>chokes, baluns (for dipoles), and a better RF ground plane (for
>monopoles) than to add RF transceiver grounding.
>
You are looking at half the circuit in isolation - and this is symptomatic of the poor discussion already in progress. You would do well to read what follows and reappraise your question in light of the mechanics that have been left undiscussed until now.

>Jason Hsu, AG4DG
>jason_hsu_802701@@@yahoo.com
>http://www.jasonhsu.com/ham_radio.html

Hi Jason,

A better balance of questions this time out.

The issue of Common Mode has been handled very poorly here in that it has been treated by example rather than by analysis. Or rather, the examples have been analyzed, but not the Mode.

If we take the perfect of all worlds example of a floating generator driving a balanced load (dipole); then by definition each arm of the dipole sees the earth halfway between it and the other arm. That is there is capacitive coupling to ground from one arm and then back to the other arm. This is the common voltage divider made up of equal Xc's. Given that the source's contribution to both arms is of opposite polarities, it stands to reason that then this divider presents a cancellation of polarities at the junction of the two impedances (which neatly corresponds to the ground and further reinforces its natural tendency to be "neutral"). Being a balanced system, the generator must also exhibit a balance with respect to that same ground (a point that is NEVER observed in these discussions and in fact is the least likely arrangement to be found in the shack).

The generator presents its own coupling to earth as much as any antenna, but in proportion to distance and surface area consistent with established considerations of capacitance. IF the generator is balanced, its case (the significant source of that capacitance) will also reside halfway between opposite potentials and be as neutral as the earth at the balanced feed. As both the source and load are balanced with respect to the same earth, and as both earth and the case of the source support a neutral electrical excitation, it stands to reason there will be no current flow in this loop that contains earth.

THIS is the definition of the complete Common Mode path which to this point has NEVER been fully described by anyone except Roy. I will accept no muttered rebukes and cries of foul or displays of angst or outrage - you fellows have done a remarkably poor job in both description and analysis.

Now if we tip the dipole at some angle to earth that is not parallel to earth, we then find an imbalance (literally and figuratively). The

ratios of those Xc's change by this action (which could be provoked by any number of means). With the change of those Xc's, the bulk Xc from one dipole arm to the other has not actually changed (the two caps in series will equate to the same value regardless of balance). However, as a voltage divider, the earth now is not longer neutral in the scheme of things (this is a facile explanation, but serves for the moment) as one arm is closer, the other further away (just like adjusting the control of a bridge balance). The source's characteristics have not changed, the case is still at 0 potential with respect to its balanced output, but that is not to say that the earth, now elevated, does not impart some current to that 0 potential surface. The Common Mode potential is now non zero, and the path now supports a non-zero Common Mode current.

This is an unique instance where the source provides the excitation to the load which in turn provides the excitation back to the source. Common Mode problems are not confined to the rig being the source however, this is simply ONE of many common problems. Any nearby radiator can easily provoke problems that are equally identifiable as being Common Mode in origin. One obvious example is Intermod due to corroded antenna components (the mixing of the principal signal with another foreign source in the structure's poor contacts). Common Mode problems of hum and noise mixed into audio paths (otherwise known as "ground loops") is exactly the same issue working at another frequency employing the simple constraints of paths, balance, and impedances.

Now, as I admitted above, my "facile" explanation is not technically rigorous (but is far more inclusive than the discussion to this point!). That is, the imbalance to the dipole is bound to cast some effect back into the source. This adds to the complexity of the analysis (and no one has ever gotten that far anyway), but does nothing to upset the characterization of the COMPLETE discussion.

This is a very simple circuit to have taken this long to be discussed in its entirety.

Joe:

That question is almost impossible to answer thoroughly. It is a little easier at HF, where no "slot" caused by gaps between contact points should be no longer than an eighth wave (about 4 feet on 10 meters). The IMD problem, however is almost intractable. A group I work with has been called in to clean up some roof structures where simultaneous transmit and receive on different frequencies and different systems are required. Similar to the neighbors being able to watch TV while you transmit. There, we often find it necessary to essentially eliminate any RF current which flows from one piece of metal to another. We have found the most successful approach is to insulate all the component pieces of metal from each other and provide a separate ground plane above the structures which then also acts as a shield. Not easy or cheap.

1) I am looking at building a 3mtr square loop for 40+80.......can you
help?

(2) I am using a program for the design of the loop and have gone for
15mm
copper pipe at 3mtrs square......now thats 12mtr in all......is it best to
make it
10mtr in all....ie 80mtr 40mtr 20mtr 10mtr.... or is it best to
have the most metal you can....?.

(3) I intend to mount this on an inside wall with pipe clips with the
base at 2.5mtrs high....is this ok.....?

(4) I have read about the fact that the voltage can be upto 6kv on the
cap...for safty reasons
what is the voltage at other points in the square loop....this is
important..and have not found
an answer yet

(5) when I make up the 1/5 coupling loop I can see the braids connect at the
start then it says
at the ends join the inner of the 1 to the outer of the other, no problem
......but the coax joined...has it got
an inner or have you got to pull it out and leave only the braid in that
joined half......

Now I know that many of you have done this before and I have read what I
can so far, any help will be welcome...........

Actually, one more idea would be the Remote Balun from Radio Works. You can see it at their web site. It serves as a transposition between coax and twin lead. So you could locate the balun outdoors. Run coax from it, indoors, to a tuner, or to your rig. As I indicated, coax might or might not protect you from EMI from a computer. Also, I'm not sure you could connect a single, long wire to the "twin-lead" side of the balun. Maybe the long wire to one side, and the ground to the other? You might ask the folks at Radio Works.

>
Here are the things I have against RF transceiver grounding:
1. It requires going to the trouble of burying an 8-foot metal rod in
the ground. Not everyone can do this.
2. The alternative to the above solution is resonant 1/4 wavelength
counterpoise wires. For my Screwdriver antenna, I would need EIGHT
wires spreading out in different directions (in order to avoid mutual
coupling). Do you really think I have room for THIS MANY resonant
wires spread out? If I had room for this many wires, shouldn't I use
them in the antenna's ground plane (which as attached to the
feedpoint)? This would work wonders in reducing ground resistance
(which means higher efficiency).
3. New hams are told that they cannot operate without having their
transceivers grounded. Do HF newbies need yet ANOTHER reason to be
scared away?
4. Nobody has a clear explanation on why RF transceiver grounding is
needed. All I have heard are vague statements that it is needed to
prevent RF feedback that makes metal surfaces RF-hot and distorts the
microphone's audio. While _The ARRL Antenna Book_ and other sources
have clear explanations on why larger antennas are better and why RF
ground planes for the antenna are needed, I have yet to see a good
explanation on why RF transceiver grounding is needed. For example,
where does the stray RF come from? Why isn't it enough simply to move
the antenna further away, use a better RF ground plane, and use RF
chokes/baluns on the coax?
5. If I'm wrong, then I expect you to enlighten me or point me to a
source that will.
6. Even if I'm right, I might as well learn more about the related
issues anyway.

|>
|Here are the things I have against RF transceiver grounding:
|1. It requires going to the trouble of burying an 8-foot metal rod in
|the ground. Not everyone can do this.

An eight foot ground rod is not an rf ground.

|2. The alternative to the above solution is resonant 1/4 wavelength
|counterpoise wires. For my Screwdriver antenna, I would need EIGHT
|wires spreading out in different directions (in order to avoid mutual
|coupling). Do you really think I have room for THIS MANY resonant
|wires spread out? If I had room for this many wires, shouldn't I use
|them in the antenna's ground plane (which as attached to the
|feedpoint)? This would work wonders in reducing ground resistance
|(which means higher efficiency).

Yes, an rf ground, if one is needed to complete the antennna should be at the
antenna.

|3. New hams are told that they cannot operate without having their
|transceivers grounded. Do HF newbies need yet ANOTHER reason to be
|scared away?

An AC ground is needed for safety purposes. A lightning ground is need for
safety purposes. Neither of these are necessarily rf grounds.

|4. Nobody has a clear explanation on why RF transceiver grounding is
|needed. All I have heard are vague statements that it is needed to
|prevent RF feedback that makes metal surfaces RF-hot and distorts the
|microphone's audio. While _The ARRL Antenna Book_ and other sources
|have clear explanations on why larger antennas are better and why RF
|ground planes for the antenna are needed, I have yet to see a good
|explanation on why RF transceiver grounding is needed. For example,
|where does the stray RF come from? Why isn't it enough simply to move
|the antenna further away, use a better RF ground plane, and use RF

|chokes/baluns on the coax?

It is often "enough" to eliminate the common-mode rf at the antenna. However, it is not unheard of for the "common-mode" rf to reappear. For instance, my two meter EME antenna was 100 feet from the shack and fed with a buried coax. When the antenna, excited with a KW or so, pointed at my shack, I had "rf feedback" (a bad term) that required mitigation by some additional suppression measures. The incorporation of a 10' foot "ground" wire to an 8' ground rod was not one of them.

Greetings,

I'd like to ask the ng's advise pro or con on which
would be *your* choice and why if this was the choice:

1. Install a 1/4 wave 160M with 70ft. vert. plus top-load

or

2. Do a "crazy" Inverted L where the horizontal portion
could *not* be straight or completely horizontal, but
would need to zig-zig in several sections back and
forth or up and down to make the required 1/4 wave.

I hope number 2 makes sense. Thx.

577. Re: Problem with 2m antenna tuning

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-14 02:14:30 UTC
From: D&K Rushworth <rushworth@iprimus.com.au>
Message-ID: <3bc8f51f$1@news.iprimus.com.au>
Source record: 156130

I've made some changes:

- trimmed the elements 1/4"
- lengthened the gamma rod to 7"
- changed the variable cap to 47pF fixed
- moved the shorting bar to the far end of the gamma rod

After all the above, the antenna tunes to 1.4:1 at 147.000MHz and increases to 2:1 at 148MHz stays at 1.6:1 below 147MHz.

One point I didn't think of. . . although I am using wooden dowl to mount the antenna, the RG8 coax is taped to the dowl so the shield will possibly be interfering with the antenna as it runs between the lower half elements 4 and 5. This may explain why it works well on the ground (coax is coming from behind the antenna) compared to when it's in its final operating position.

Jason- to cut to the chase, as the old movie directors said- the basic problem seems to be one of understanding and definitions. Equating the need for an RF ground with the need for an 8' rod is one, for starters. Beyond that, and to answer your #4, below- please read the posting from Richard Clark, dated today, at 18:21:03 GMT. He is one of the clearer thinkers, with more grasp of fundamentals, and a lucid writing style. He has no axes to grind, except those that are designed to chop down crap. Read his stuff, and keep up with what he says- he's good.

I have used several hundred feet of the 3/16" kevlar rope from RadioWorks over the years with no sign of deterioration. I use it for halyards to haul the antenna lines through the pulleys. To support the pulleys in the tree, I use the 3/8" black dacron from the same source that others have suggested. However, I think that the 3/16" kevlar would be adequate for that as well. It has about 700# breaking strength which is more than adequate for any wire antenna I can put up. <:}

Almost any large computer store has cigarette lighter adapters

for laptops. Radio Shack has one (some?). Compuserve, Best Buy,
and Circuit City might have them. Be sure to get the wattage
right. I run my entire ham rig, including the SCS modem and
laptop from a 12vdc deep-discharge battery charged by my Astron.
An AC power failure doesn't even cause a hiccup.

> unbalanced and can thus have common mode currents?
The output of a transmitter is differential so there are actually

two paths. A balanced antenna, like a dipole, provide those two
paths for the differential current. Even an unbalanced antenna,
like a vertical with radials, provides those two paths for the
differential current. In these cases, one doesn't necessarily
need to provide a ground. (What I am saying has nothing to do
with lightening protection.)

An end-fed long-wire provides only one obvious path for the
differential current. This is when it is advisable to provide
the "other half of the antenna" in the form of a ground and/or
a counterpoise, preferably at the antenna but it can be done
at the transmitter. For a differential source, the current
going somewhere needs to be balanced by a current coming
from somewhere and vice versa.

> antenna

If you are not driving a folded dipole with it, you don't need
a 6:1 balun. If you are carrying a relatively high SWR on your
300 ohm feedline, the balun will NEVER see 300 ohms. Most hams
use a 1:1 current balun/choke or a 4:1 current balun/choke for
this application.

I have a 33ft rotatable dipole fed with 300 ohm ladder-line
that I use on 20m-10m and I use a 1:1 current balun/choke.

For feedlines carrying an SWR greater than 1:1, we will never
see the characteristic impedance of the feedline as a load at
the transmitter end. For instance, if the SWR on your 300 ohm
feedline is 6:1, you may see 50 ohms (300/6) or 1800 ohms (300*6)
but you will NEVER see 300 ohms purely resistive.

>hello out there has somebody any plan for homemade 6:1 balun?

I have a factory made 1:6 balun for my Inverted V off-center-fed antenna (made by an Italian company 'ECO Antenna' from the city of Serravale). It is 635 plus 1405 centimeters long and works on 40-20-21 and 28 meters with an SWR under 1.5 on all those bands. The off-center feedpoint is about 300 ohms for all those bands. The V-angle at the supporting pole in the middle is 120 degrees. The balun is factory made and hermetically sealed in a plastic box. I was curious so I opened it. Well, instead of a 1:4 transformer (1:2 turns ratio), I found a 1:2,45 turns ratio (square root of 6). The toroid was 4 centimeters in diameter with 6+9 turns of thick insulated wire. The middle tap went to the coax braid; the center lead of the 50 ohm coax went to the end of the shorter coil and to the shorter arm of the antenna, and the longer coil went to the longer arm of the antenna. I have only 23 meters of space on the flat roof of my condo (20 x 10 m), so I am very satisfied with that antenna and its balun.

> has somebody any plan for homemade 6:1 balun?
> thank's alot

I have an inverted-V off-center-fed multiband antenna for 40-20-15 and 10 meters. Its shorter arm is 635 centimeters long, and its longer arm is 1405 centimeters long. At the feedpoint it has a 1:6 balun and about 300 ohms impedance on all those bands. The inverted V angle in the middle at the supporting pole is 120 degrees. The antenna and its balun was made by an Italian, little known, company: Bordino Rinaldo & C. s.n.c., Fraz. Serravale, 14020 Serravale (ASTI)- Italy. (I bought it some 10 years ago, so I am not sure if they still exist.) The balun was hermetically sealed in a thick plastic box, but I was curious, so I opened it. Instead of the usual 1:2 turns ratio (i.e. 1:4 balun) I found a 1:2.45 turns ratio (the square root of 6): 6 turns plus 9 turns of thick insulated wire on a big toroid 4 cm in diameter. The middle tap went to the 50 ohm coax braid and the center lead of the coax went to the end of the 6 turns coil and to the shorter arm of the antenna, as well - while the end of the longer coil went to the longer arm of the antenna.

The antenna works with less than 1.5 SWR on all those bands. I have only 23 meters of space on the flat roof of my condo (20 x 10 meters), so the antenna just fits there. I am very satisfied with that antenna and its balun.

How do you keep the Astron (I know what an Astron powersupply is) from overcharging the deep-cycle battery? Timer? If timer, then how do you know if the battery is back up to full charge when the timer kicks off? Hmmmm, the proper charge controller from a photovoltaic (PV) panel could be the answer.

[snip]

Careful... dragons wait beyond...

Nominally may be in the eye of the beholder. And often the "nominal"
point is not physically obvious.

Should a current [Guanella] balun wound on its' core with bifilar/"two in
hand" parallel transmission line be considered a lumped device or a
transmission line device? What about a current balun "wound" with coaxial
transmission line?

And... precisely where, along the transmission lines within the balun
itself, does the conversion from balanced to unbalanced occur?

And... is a coaxial system [cylindrical symmetry] inherently any more
unbalanced than a balanced system [rectangular symmetry]?

I'm sure that you know that... common modes include distributed elements,
i.e. transmission lines, and lumped elements just as differential modes do.
And that... common mode transmission lines transform the impedances seen
"through" them just as differential transmission lines. A common mode
impedance seen here may be quite difference a "few" feet away...

But then I know that you know all of this.

Best,

--Peter K1PO

13.8vdc will NOT overcharge a 12v battery. (13.8vdc will not
even fully charge a 12v battery.) That's the beauty of paralleling
a battery with a 13.8vdc supply. That's why power supplies are
preferable to chargers for such an application.

Sorry, I forgot about off-center-fed dipoles. I should have said,
"Unless your antenna has a 300 ohm feedpoint impedance, you don't
need a 6:1 balun."

595. Cushcraft DX-120 2 meter array question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-14 14:22:59 UTC
From: Bill Russell <willy@global2000.net>
Message-ID: <4i7jst8gu9qadbnkrbrnt1qlg5phji27pa@4ax.com>
Source record: 156148

I just purchased this antenna at a local ham fest and know nothing about it. It has never been assembled and is "in the box". Has anyone used this 2 meter array and if so how does it perform. The instruction sheets that came with the antenna do not list the specs for the antenna so I have no idea what to expect.

Thanks in advance,
Bill KC2IFR

|--Peter K1PO

I just started looking at this tread so forgive me if this is not timely.

I have used a couple of small Statpower inverters, see:

http://www.statpower.com/home.htm

These are sold a lot a RV/Camper supply stores,ie, Camper World.

If you are interested, a hot tip. Don't buy at Camper World, check out:

http://www.store4power.com

and look at their "Factory Outlet." They have "remanufactured" close out specials that are often 1/2 price. Right now they have their "True Charge" line available. These are microprocessor-controlled three step chargers.

Now, a war story (ongoing). I have a 25' fifth-wheel travel trailer that has a build-in 30A switch-mode charger. This was made by Todd Engineering, now out of business. It is a dual-voltage charger that uses a manual switch to go from "charge" to "float". In the summer of last year, we traveled for three months (our first post-retirement trip) and I took along my TS-870 so as to keep skeds with friends back home.

Often, while connected to shore power (charging) I was plagued by strong noise on various frequencies. I learned that if I flipped the charge voltage switch, the change in voltage would cause the noise to change frequency and stop QRNing me.

Here at home, we are located outside of Tucson and our "local" TV stations, while at 8800' ASL are non-line-of-sight. I discovered that while charging the trailer batteries, I have severe noise on CH 4 TV.

I presently have this charger on the workbench trying to surpress the rfi. So far I have had very little success. I won't go into the details here, as that could be another thread, but rfi from switch-mode chargers/inverters should be a consideration in your selection.

I am considering a completely analog charger if I can figure out where to physically located it. For the homebrewer, TI (formerly Unitrode) makes a specialized IC (UC-3906) that implements dual-stage charging (analog) for lead-acid batteries. See:

http://focus.ti.com/docs/prod/productfolder.jhtml?genericPartNumber=UC3906&pfsection=app_note

73,

Wes N7WS

ps. For last Field Day, I used my Astron supply in parallel with a deep-cycle battery and powered the Astron with a very old gas-power generator(alternator). When the generator ran out of gas (often) I was still on the air.

597. Re: CAN I TUNE A BUILDING????????

Source record: 156150

On the subject of computers interfering with radios...

Obviously, in a world a bit closer to ideal, the interference should be getting into the radio by way of the antenna jack. It's best not to install your PC at the top of your tower...

If the noise is getting into the radio directly through the side of the radio's cheap, plastic, unshielded case, or by way of the microphone cord, or whatever..., then that is *just terrible* !

de VE1BLL@rac.ca /VE3

PS: Reminds me of the time a guy told me that the car ignition interference was obviously getting into his CB set by way of the 12V power wiring. I asked him how he could be so sure - he explained that when he disconnected the power, the noise went away.

598. Info needed: Maldol HS-VK5JR

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-14 15:33:36 UTC
From: Michael Sell <k0com@earthlink.net>
Message-ID: <3BC9AF0F.EA4DA822@earthlink.net>
Source record: 156151

This is a multi band vertical for the HF bands. I am looking for an instruction manual to assemble and tune this antenna. I got the antenna from an estate sale. It was taken apart, and it was painted black. The only thing I can read on the antenna is the brand, Maldol. I did find this model on an Italian web site, that 's how I found the model number. It is very very simular to the Diamond CP6, although Diamond claims it is NOT the same antenna. No current Maldol dealers seems to have any info. It looks like Comet antenna's has something to do with importing the Maldol brand these days. Can anyone help?

Thanks
M. Sell

Many moons ago when packet was young we put a digipeater, Xerox 820
board with Karns software, on a mountain top. We used auto battery power
with a "on demand" charger designed by another ham. As memory serves me
he designed a pulse charger. It monitored voltage/current and adjusted
the PWM to supply more or less charge. It ran great for a number of
years.
The only problem was we were "guests" at a voice repeater site and every
so often the owner would unplug our line power to plug in a piece of
test equipment and not plug it back in. After several days we would hear
the signal "motorboating", a sure sign of low voltage. And since it was
usually winter when he did it and there was snow up there, and I had the
only 4x4, guess who got to blow an afternoon driving up to simply plug
in the AC line cord.

Why would anyone provide the grounding/counterpoise at the transmitter
when providing it at the antenna feedpoint would reduce ground losses
and thus enhance efficiency?

I'll bet this has to do with ground conductivity limitations. Now
that you made me think about this, if a ground rod is not very
effective in reducing the antenna's ground resistance, one must wonder
how useful it would be for RF transceiver grounding.

>
> Yes, an rf ground, if one is needed to complete the antennna should be at the
> antenna.
>
Agreed.
>
> An AC ground is needed for safety purposes. A lightning ground is need for
> safety purposes. Neither of these are necessarily rf grounds.
>
Agreed.

< It is often "enough" to eliminate the common-mode rf at the antenna.
However, it is not unheard of for the "common-mode" rf to reappear.
For instance, my two meter EME antenna was 100 feet from the shack and
fed with a buried coax. When the antenna, excited with a KW or so,
pointed at my shack, I had "rf feedback" (a bad term) that required
mitigation by some additional suppression measures. The incorporation
of a 10' foot "ground" wire to an 8' ground rod was not one of them. >

How did the common-mode RF reappear? What is a better term for "RF
feedback"? What did it take (other than pointing the antenna in a
different direction) to remedy the problems you had when you pointed
the EME antenna towards you?

Wes:

Hey thanks for all that great inverter information. I'll make good use of it.

Re: My Sony VAIO laptop. It uses Lithium Ion batteries, I don't know what the charging voltage should be for these. The "charger" that comes with it takes 110 - 240 VAC on the "mains" side, and produces 19.5VDC on the laptop/DC side. I don't know much about Li Ion battery technology. I am wondering if it's possible to charge the laptop's Li Ion batteries directly from the car battery without resorting to an inverter to go from 12VDC up to 110VAC and back down to 19.5VDC.

Best,

Big Hi, Hi. After I posted that last nite I tried to bust the pileup
for KC4AAA on 14.265 only to find my words coming out through my
(supposedly) shielded PC speakers. Was putting out about 600W
at the time. I thought my headphone jack was failing and it was coming
from the internal speaker on the rig until I took the headphones off !

AS to quiet PCs,.......Well if Ashcroft has his way and we start losing
the privacy rights that I thought we were fighting to protect, then maybe
I will get around to putting up that Faraday Cage<sigh, grin>.

I think the answer is how permanet does it have to be. As wire stretches,
you may want to bring it back down to clip it some more. Aging and growth
of Big Trees may give you new "openings" for better placement. The Dacron
is awesome, but the only times I've had antenna come down it wasn't the rope.
Instead it was 14AWG stranded, insulated that snapped twice under winter
storm load-- The clothesline rope was still hanging. Wire was dog-legged
around 3 trees and that was bigger strain then cheap rope.

Bottm line: Don't worry too much unless this is one you've got to live with a
long time. I don't even permanently anchor mine; They're weighted with flagging
stones until I'm happy with SWR, Imp., Azimuth and height. Then I'll tie them
off. Remember: By itself, rope contributes nothing to signal reports.

Is that (^) a rhetorical question ?

I hope that you're not 'saying' that you need 'a name' and some
"credentials" to critique something that happens to have been "published".
I've seen things put between covers that could be deflated with a simple
rhetorical question.

So just WHO IS this Kurt Sturba anyway ?

John,

You can make a dipole antenna. I'm sure you know how to do it (are you a licensed HAM?). MFJ sells wire antenna's for the 6 meter band, complete with coaxcable and maybe even a connector so you can plug and play. MFJ-1736 (J-pole) and MFJ-1764 (dipole)

|I'll bet this has to do with ground conductivity limitations. Now
|that you made me think about this, if a ground rod is not very
|effective in reducing the antenna's ground resistance, one must wonder
|how useful it would be for RF transceiver grounding.

Let's pretend we drop the 8' rod into sea water. We connect to it via an 8 foot, AWG 6 wire to the wingnut on the back of a 10 meter transmitter. Question: What is the impedance to ground of this "nearly perfect" ground system?

|
[snip]
|
|How did the common-mode RF reappear? What is a better term for "RF
|feedback"? What did it take (other than pointing the antenna in a
|different direction) to remedy the problems you had when you pointed
|the EME antenna towards you?

While it's not the best term to use in this discussion, "common-mode" in this thread has been referring to currents on the outside of the unbalanced transmission line that are not balanced with respect to the inside of the line. By this definition, if by radiation from the antenna, currents of this type are induced onto the transmission line, equipment enclosure, microphone cable, etc., they can be called "common-mode". They are really differential mode with respect to earth.

The usual techniques of additional shielding, ferrite beads, bypass capacitors, etc, were used to cure the problem.

"RF feedback" occurs within rf amplifiers and can either be positive, giving rise to oscillation and/or instability or negative, helping lower gain and/or distortion.

What is commonly called rf feedback is usually rf getting into audio or control circuit lines and being rectified and causing instability. In this case the problem is caused by the rectified signal (which is no longer rf), not the rf signal itself.

Hi Jason,

Grounding, aside from the safety aspect, provides a reference. In
that reference is also an enforcement of stability and control. If
you suffer a hot chassis and you ground it, the voltage goes away
(says nothing of the current however). You will never be bit again
with respect to this reference (and you do spend a lot of your life at
ground potential).

You can of course insure that your system is balanced, pull the ground
lead and note not a hair disturbed by hot equipment. And then the
wind blows a limb over your dipole - Zap. Now as I have already
dismissed the safety issue, the Zap is more significant of combining
other equipment by making connections. That balanced system must now
embrace a larger context (a fantasy), or the artifice of balance needs
to be nailed to ground. It would have made no difference to have that
ground wire installed with the balanced system. In other words, no
need to remove it either. There is an advantage to this.

There is nothing efficiency based in this at all, and within the
confines of this discussion, efficiency is NOT a determinant of
efficacy.

Even with remotely located antennas, computer 'noise" or
other RFI can be carried from the shack back to the antenna
on the surface of the coax shield. A common mode ferrite
choke on the coax, and a good ground, can help choke off
common-mode noise pickup from equipment in the shack.

Take a typical long-wire configuration - a single wire run from

the top of a chimney close to the shack. The feedline runs up
the chimney. Where are you going to get an RF ground 25ft in the
air? Where are you going to run your counterpoise? The reason
you have the long-wire in the first place is that you don't have
room for a center-fed dipole.

Hardly, "J" <:} Long ago, I reached a degree of professional and intellectual maturity that permits me to rather quickly spot the "real stuff" from the trash.

I was merely commenting in my usual arcane and tangential manner on the notion that someone would appear to mention "Kurt Sturba" as an authority in the field of antennas and lines in a posting concerning the integrity and validity of ARRL publications.

To my knowledge his actual identity has never been revealed although many folks are convinced that he is Armond Noble who publishes World Radio.

I read "Kurt's" columns from time to time and tend to agree with him on most of his observations, but an "authority" ? - hardly. I still prefer to gain inspiration and knowledge from Prof. Terman, the immortal W8JK, Walt Maxwell, Roy Lewallen, and others, including those who publish extensively in ARRL and RSGB publications and occasionally on this newsgroup.

628. Dual yagis, but not phased...possible?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-14 20:58:16 UTC
From: theshearers@worldnet.att.net
Message-ID: <3BC9FAC9.1E610A06@worldnet.att.net>
Source record: 155932

I am looking into installing some 902-908 mhz band FHSS data radios soon. One of these will function as a repeater in addition to being a data gathering unit. This unit will send data back to the base (15 miles) but will also repeat data coming from another unit even farther away (another 10 miles). I have a 100 foot high building at the base station, and phone poles at the remote locations. The terrain between still has to be investigated to check if this system is even feasible (in a one hop straight line path!). BTW, the power is 1 watt and is an unlicensed service.

The plan is to use a single radio unit in the center of the link with 2 antennas. I hope to build a phasing harness to feed two 10 dB yagis properly, but seperate the antennas and aim them in almost opposite directions. If they are seperated enough or screened from each other would there be an interaction problem? There is no problem with transmitting the data content in both directions. Has anyone done this, or is this commonly done?

Thanks, Tim KF8XW

The DX-120 is a collinear antenna that several of the big signal
2 meter moon bouncers have used by placing many of them (8 or more) on a
large, movable frame where they are all aligned on the same plane.

They are relatively broad band antennas with good gain, front-to-back,
and use the mast as the boom for single unit height advantages.

GL!

631. Delta Loop Questions

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-14 22:03:27 UTC
From: Lew <lew_jean@mindspring.com>
Message-ID: <9qcnin$ls4$1@slb7.atl.mindspring.net>
Source record: 155924

Since I rent, I am limted on what I can put up,
I have just set up my Tempo 2020 and want to get working antenna
before I get a new rig (Yeasy FT-840)

I am looking at a triangle loop (have never played with loops before)

Base of triangle 6ft long (9ft above ground & 6ft from house)
Each side triangle 16ft long (approx 20ft above ground)
Top feed next to building (5" from building)
From top to bottom the loop will have about 30 degree slope

Feed with Coax 50 ohm or 2 pices coax (shields tied together) center going
to the loop, have a tunner at radio end

If I made 4 turns using insulated wire around the loop, (1 loop = 38ft)
Will this idea work for 10-80 meters

Also any comments on the Yeasu Ft-840 would be great

Please respond via email (can not always get into the news groups)

Thank you for your time

YOu can do this. What you are calling a phasing harness is really just
a matching segment. Unless the beams are facing close to the same
direction and you want a clean patern or maximum gain in one direction
the phasing will not make much differance. You will be splitting the
power so tha half the power will be going to each beam.
This works fine for stations in differant directions.

I have a Rohn 25G tower that's about 35 feet high, currently with nothing on it.

I would like to add one section to it to get 45 feet of height, then install a Diamond X-3200A 2M / 220 / 440 vertical on top.

THEN ... I'd like to feed the base of the tower, using a gamma match or shunt feed, and use the tower itself as a vertical on 75-80 meters.

I would imagine I could use some sort of capacity hat at the top of the tower to help load it.

I'd like to be able to feed 100 watts or so into the tower, while using the VHF/UHF rig and antenna at the same time.

Can any of you direct me to some books, websites, or magazine articles that discuss this and explain the hazards and design issues involved?

I don't have a problem with the part about feeding the tower ... I can probably figure out how to do that the right way ... but I don't know what the interaction will be between a "hot" tower and the VHF/UHF antenna on top, with a coax (whose shield is at DC ground and at who-knows-what RF potential) running the length of the 75-meter radiator.

Thanks for any advice you can offer...

Eric

Good point, I did not think about the power split. I believe there is a gain margin built into this kind of equipment (coding gain) and maybe the 3dB loss could be made up for. The units can read signal and noise levels at the receivers. I plan to do a test over the paths to verify signals, before all the $$ are spent (however the leaves are falling now, so the attenuation factors will not be at maximum until next summer!).

635. Screwdriver antenna on motorhome

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-14 22:59:20 UTC
From: vtail@hotmail.com
Message-ID: <3bca167d.527128766@news.netis.com>
Source record: 155940

My motorhome is fiberglass body, unknown body frame (might be wood, might be aluminum), and aluminum roof.

I am considering mounting a screwdriver-type antenna for 80-10 meter use. This antenna will NOT be used while in motion, only while stationary.

Hre's my plan ... please tell me what you think.

Mount a mast to the rear bumper, and run it up so that the top of it is just above the roof line.

Fasten a metal plate to the top of the mast and fasten the other end of the plate to the aluminum roof using sheet metal screws or some other kind of fastener.

Mount the screwdriver antenna on top of the mast, and coax-feed it at that point.

Mount two 102" stainless steel CB whip antennas horizontally near the top of the mast, one pointing rearward from the motorhome, and the other pointing to the side, away from the motorhome. These then become part of the ground plane.

This would all be relatively easy to assemble when parked and disassemble for transport (perhaps 10 minutes to assemble or disassemble).

Does this sound like a reasonable approach? Am I likely to gain enough from the additional ground plane (the two 102" horizontal whips) to make them worth the bother?

Thanks...

Eric

Source record: 155939

The main error in working with multi-element antennas when the analysis program limits the number of segment is in the F/B ratio. The forward gain and the associated main lobe are almost always of acceptable accuracy. The drive resistance is usuallly acceptable, but the reactance less so. This means that the frequency for best F/B is off a little.

Two cures are available. 1) run several simulations, starting with a small number of segments, and increasing towards the maximum allowed by the program; if the results appear to converge towards a constant value, the results are very dependable: 2) Program variations usually called 'professional' can handle very large to unlimited number of segments; They tend to be expensive, but perhaps you have a friend in a school of other lab you can work with.

That is true.

Kurt N. Sterba is a play on words for Sterba Curtain, a type of antenna designed by E. J. Sterba of Bell Laboratories. (BTW, as I understand it, Sterba was the boss of Philip Smith of Smith Chart fame.)

Put up 160M G5rv home brew. Was waste of time except on 40M. Almost took down but tried 230' of wire connected to far ends, then hoisted up in a large square in the pine trees about 110 ft. per leg.
Outstanding performance on 160-6 meters. Have taken down the vertical loops and only kept 250' end fed for parasitic.
Wish I tried this antenna years ago. It is slightly less than full wave on 160 but works just fine, even the weak ones ona ll bands answer now..

I've done a lot of snipping in my reply - I tried to retain
the context, and hope I succeeded.

Sylvan Butler wrote:

<snip>

> Sounds good. And so we treat the "grounding electrode system" as a
> unit for safety ground, and maybe for lightning?

Yes - but we don't have the option of selecting how we treat it.
Electrical code specifies what it is.

> In other words, if
> a grounding electrode system consists of a single ground rod you
> connect to that rod.

Well ... no, I would add at least one supplementary electrode. Current
code requires at least one supplemental electrode, so if you want
effective grounding of your ham station, which is the point of this
discussion, adding at least one electriode would be called for.

> If it consists of a dozen rods properly
> bonded, you can connect to any one of them.

Yes - your "same point" ground can connect to any one.

> > If you have 250[ft] between two electrically connected pieces
> > of equipment, each of which requires a ground, "same point"
> > grounding as described above isn't possible/practical. Therefore,
>
> That's what I thought. At what distance does it become practical?
> It is practical at 1ft. What about 10ft? 20ft? At 100ft?

What is practical will depend on the individual situation.

<snip>

> > In all cases, what you do with respect
> > to grounding must not violate the electrical code.
>
> For practical purposes, yes. But when things start getting
> esoteric... That is where engineering comes in.

Nope. In all cases, whether engineering is involved or not,
what you do with respect to grounding must not violate
the electrical code.

<snip>

> > As mentioned before, the NEC
> > (or applicable electrical code) must be followed. In the NEC,

> > could not be supplied with a branch circuit. Instead it would
>
> A 200amp fault current is still a possible branch circuit. And it
> may be used for a 200amp load or split via a sub-panel per requirements.

Nope. We're talking a ham radio setup in the building. You cannot
supply that equipment on a 200 amp branch circuit. Going further,
assume the outbuilding houses a 200 amp load, and no ham equipment.
You still can't have a single 200 amp branch. Single is the important
factor, as we are discussing whether or not an electrode is required.
With a 200 amp load, you will be required to provide additional
circuit(s) for lighting & maintenance - so you will have to have at least
one additional "branch". And you have never seen a 200 amp
branch circuit in a residential installation - it doesn't apply here at all.

In addition, you may not split a branch circuit via a sub panel.
By definition, it will no longer be a branch circuit. A branch circuit
is defined as the circuit conductors between the final overcurrent
device protecting the circuit and the outlet(s).

> > supplied by a feeder, would have to have a sub-panel,
>
> Only if necessary to split the 200amp branch circuit.

Please. The 200 amp branch circuit is fiction and not splitable.
We're running a ham station in a shed. If the shed also houses a
bunch of heavy equipment and needs a 200 amp feeder - or has
this mythical 200 amp branch, you don't need to worry about
"same point" grounding if you don't know how to properly ground
for that expected 200 amp fault current.

> > and would
> > need a grounding electrode.
>
> As a seperate building, the NEC allows a grounding electrode

No. The NEC *requires*, not allows, a grounding electrode for that
building, with only 1 exception: when the building is served by only
1 branch circuit.

> <snip> At that point adding a grounding electrode seems to
> be optional. I believe it desirable, but I don't believe it required.

No - see below. 250-32 in the 1999 NEC
<snip>

> Hmm. I think the question still stands: Should I add a grounding
> electrode bonded to the original GES and connect to that, or should
> I just connect to the original GES? When the NEC is silent, how do

> you decide?

The NEC is not silent on this - unless you have only one branch
circuit going to the outbuilding. Even then, it does "speak" telling
you yopu are not required to add a grounding electrode at that
building.
<snip>

> > circuit. If you have multiple branch circuits, NEC requires a ground
> > electrode.
>
> I don't recall that from the 1999 book I have for my jurisdiction.

See 250-32 (a) in the 1999 NEC:
"Where two or more buildings or structures are supplied from a
common ac service by a feeder(s) or branch circuit(s), the grounding
electrode(s) required in Part C of this article at each building or structure
shall be connected in the manner specified in (b) or (c). Where there are
no existing grounding electrodes, the grounding electrode(s) required in
Part C of this article shall be installed."
"Excdeption: A grounding electrode at separate buildings or structures shall
not be required where only one branch circuit supplies the building
or structure and the branch circuit includes an equipment grounding
conductor for grounding the noncurrent-carrying parts of all equipment."
See 250-50 & 52 for part C. Without quoting it, the electrode is the
ground rod we've been talking about. (It could be any of the made
electrodes mentioned in 250-52)

Hi Angelo

Look at www.antennex.com.
They have a bunch of good stuff on magloops.

My experience with single-band magloops (dont have motor tuning of capacitor yet) is that they work. The S-meter on my TS-430S actually moves!

Make sure you have very low resistance in the loop and the tuning capacitor. The capacitor is generally the most difficult part. There are several good solutions available, but generally with a cost, time, skill tradeoff.....Try it at first with any variable capacitor just to get your feet wet, but the performance will be way down compared to a low-loss low-resistance variable capacitor.

I have tried feeding the loop with Faraday loop and gamma match. The Faraday loop works, but seems to be tempermental and the match varies from day to day. The gamma match seems much more stable. I have converted my loops to gamma match.

My loops are mounted on stands made from PVC pipe that I can carry out to the backyard and back to the garage easily.

Have fun.

Yup. I screwed that up. I meant to say "Note that in all of the
above, you must not connect the ground point of the equipment
to the "same point" ground you are building *rather than the receptacle
ground*, if that equipment`s ground point is already connected to
ground via a 3-wire power cord." I've heard that some people
cripple the 3 prong plug, trying to avoid ground loops. That's wrong.

It would have been simpler to say "in no case should you cripple the
grounding via the 3-wire line cord, if the equipment is already
grounded via that means", or something to that effect.

None

between a "hot" tower and the VHF/UHF
> antenna on top, with a coax (whose shield is at DC ground and at
> who-knows-what RF potential) running the length of the 75-meter
> radiator.

Just bond the shield/antenna at the top and where the coax leaves the tower.
You will need a good radial system at or near ground level, just run the
coax under it. I have a 100+ foot tower with a 2M, 440 (DB 410/224) antenna
above, plus a 6M "J" out the top of the first. I feed it on 160 with a
gamma match, and use elevated radials at 10 feet elevation. All the coax
leaves the tower below the radials. I've yet to see any interaction. By
the way, don't be disappointed if the Diamond doesn't work as well as a
commercial antenna.

> > when providing it at the antenna feedpoint would reduce ground losses
> > and thus enhance efficiency?

Jason, The feedpoint of an end fed long wire IS the transmitter,
or if using one, the transmatch.

Think about it. Say you have 130 feet of wire strung between
two trees. A 20 foot wire is connected to one end. The other
end of the 20 foot wire comes into your shack through the
window. Where are you going to put the ground?

Next: suppose you don't care about antenna efficiency?
Why would you spend any time/energy on optomizing it?
But you sure don't want RF burns that could come from
touching an RF "hot" chassis. So providing an RF ground
at the transmitter would make sense, even if you didn't care
about antenna efficiency.

Next: Suppose you wanted to experiment with different
methods of ameliorating or eliminating RF in the shack.
Why wouldn't you try adding an RF ground to the transmitter?

Next: Suppose you have a rig, and operate all bands with
no evidence of RF in the shack. Now you add a PC at the
operating position, and the monitor gets herringbones when
you transmit. Would you avoid adding an RF ground at the
transmitter if it would eliminate the problem?

Next: suppose you have a dipole for 80 meters. You decide
you want to work 160, but don't have room for a 160 meter
dipole. You could short the ends of the feedline together
and feed that through a tuner and work 160. Would you

put up with RF in the shack in that configuration rather than
adding an RF ground, assuming you could?

Next: suppose you had a high noise level. How would you
determine whether or not adding an RF ground would lessen
that?

These examples could go on and on. The point they make is
that you need to broaden your outlook on RF grounds if you
want to understand the subject. If you study RF for forty years
and then think you know everything there is to know about it,
you'll be wrong. You know almost nothing - which is fine - and
than take a strong, virtually inflexible, position - which isn't.
You make statements of fact, which aren't true. You make
statements of your observations, but they are wrong. For
exanple, you say "I have yet to see a good explanation on why
RF transceiver grounding is needed." What has actually occurred
is that you have yet to understand the good explanations you have
seen, and thus do not recognize that they are good. (I'm not
saying that every explanation you have seen is good - but some
were.) You have restricted the area where you look, and seem to
have an unfair expectation of yourself. You seem to think you can
understand this stuff by reading a few posts in the NG and the Web,
perhaps supplemented by the ARRL handbook. And you seem to
think you can get the issue resolved by asking 4 questions of the
gurus here.

I haven't made this post intentionally harsh, but I have done nothing
to soften it either. Your tone deserves a harsher response.
An example. You said: "If I'm wrong, then I expect you to enlighten
me or point me to a source that will." Where the hell do you get
off telling the people here what you expect of them? It would have
been far better to say "If I'm wrong, then I would be most grateful
if you could enlighten me or point me to a source that will."

I've read four responses you have made to people who have
answered your questions in this one thread. I did not see you
say "thank you" in any of them.

It's not all bad - in fact, I think it is primarily good. Your
enthusiasm and interest is unusual, refreshing and commendable,
in my opinion. But I think that if you change your modus operandi
you'll get better results.

Now, in anticipation of your reaction, I will go attempt to perform
the anatomical impossibility you might wish to recommend, thus
saving you the effort of telling me to do so.

Hi Karl,

Thanks for responding - and I see the validity of your points BUT do you think that the FCC (or any of those other letter agancies) would be more interested in me, or somebody trying to block VOA (or something like that in these crisis times)?

Like I said, I want to use about 1/10 of the legal power - on that "legal" experimenter's frequency to a basically untuned antenna. A free space 1/4 wavelength at 160 Khz is 1462.5 ft! I don't have a 1/10 of that length (any way that you want to slice it) to make for even a "non-gain" antenna. It's loss anyway that you want to look at it. Like I said, 1 watt and 50 ft. "vertical" is OK AND approved for experimenters. Most send out a continuous beacon from what I have read (I've never received one). I've never heard of the "power companies" ever busting one of these, legal stations. Doesn't ERP also come into play a bit here - less than legal power * crap antenna?

Is your concern because my roof is so large (not comparitively to the wavelength though) and maybe more of a "horizontal" plane radiator??? Does horizontal versus vertical polarization even make a difference AT THESE FREQUENCIES????

I never thought of the electric power companies using these frequencies to monitor their stuff. Then again, if you are the power company and have access to thousands of miles of antennas (albeit carrying a very high voltage 60 hz carrier wave), why not use them as transmitters! Do they use any of the common 3 letter call sign signifiers as the "licensed" stations on that band do - or are they just radiating unlicensed, illegal power and spurious emissions?
Yeah, I'm sure that there are government standards for that too!

Are they licensed and trying to send an "RF" message back to some monitoring point, or are they using the power transmission lines as "transmission" lines? If the second case were true, I'm sure that they'd send their signals in a balanced configuration where Common Mode signals would be rejected - much like my 1/10000 of a watt (ERP).

I knew that the "white vans" were history - and, yes, MUCH over a decade ago. I also know that the FCC is a small "shell" of it's former presence in the "white van" era. The CB bands have gone to pot as there is no longer anyone to patrol them. Pirate radio stations run rampant on MANY different frequency bands and I don't see it in my newpapers very much (if at all) when they are busted.

Art Bell had a great story a few weeks ago. He ran a 50 watt bootleg AM station 24/7 for over a year and the only reason that they got busted was because they suddenly "appeared" in the Arbitron's and the local, licensed station didn't take very kindly to that. This was like 30 years ago or something.

Locally, we had an FM pirate for almost a year in our area. The TV/Radio critic wrote about the pirate in three articles - and said he was going to alert the FCC. It would have been front page news if they had ever caught that guy - they didn't.

I don't want to seem flippant - you have a lot more letters after your name than I do. I had never thought of your angle and I've now considered it. Please expand more as to how the power company uses these extremely low band frequencies. I just think that your view of the FCC (and what they actually DO anymore) is quite a bit exaggerated.

Thanks for your time and expertise.

Paul

Good morning, George. Thanks for the info on loading the tower.

Isn't the Diamond a commercial antenna?

I'm planning on getting it because it's the only VHF base antenna I
can find in the HRO catalog that covers 2m, 220, and 440, so I can use
it with my TH-F6A. Are there other, better options that you know of
(besides having three separate antennas which of course is always an
option)?
.

Sounds neat, and , it would fit nicely at my QTH, but the numbers don't seem
to add up, so maybe you can clarify.

110' square would be total 440' of wire (330 in addition to the original
110).
It's a closed loop, right?

Paul,

Mind if I ask,.....

What's so wrong with doing this legally?
You know, get a license and go the same route most others have in the past.
There's plenty of room for experimentation - it's encouraged within the limiits
of your license. Are you aware that light is technically an amateur band? I'm
not sure but I think the current record for dx is 23 or 24 miles. Using laser,
you might be able to set a world record. Have you heard of *liquid* antennas?
Do a web-search, you'll get hits. I'm still not sure who you expect to be
talking to with 1/10 legal power in an area where all comms I've heard of were
PSK or packet (I think). Do you already have a 160Khz transmitter? Maybe
I've missed a lot here but,... What are your goals??

Thread:

My favorite antenna article from Larson E. Rapp, WIOU was the one on his famous Image Antenna...

OT's may recall that the image antenna was buried below ground.

The buried antenna then caused a virtual image high in the air above the ground. It was this elevated image that did the radiating. Of course to achieve "height" you had to bury it deeper. This was the primary disadvantage.

I forget some of the other details but there were many advantages, such as the smaller size that could be utilized due to the higher dielectric constant of the earth... and Larsen actually wound his buried antenna on a ferrite core like the ferri-loopsticks used on AM radios, so that the hole for the buried element did not have to be too big.

The most amazing thing that Larsen discovered was that the Image Antenna's radiation pattern actually had an inverse power characteristic... that is the signal strength actually increased in a square fashion with distance from the image!

Heh, heh... signals received from the Restaurant at the End of the Universe would have been much louder on Larsen's antenna than the signals from Bouvet! Douglas Adams would have liked that I am sure.

They just don't make hams like Larsen E. Rapp WIOU any more!

Best,

Here is a tip I recently put in my club's newsletter. I do not characterize this stuff as "best", but I like it. I also wanted something in at least a 500 foot spool, that was black or olive in color.

Some of the other sources of cord are pricey. The price is US dollars, shipped within USA.

"After searching far and wide for a low visibility "camo" rope to use for antenna supports in my trees, I found a roll of olive drab nylon "parachute cord" available through Cabellas for the price of $34.99 for a 1000 foot spool (about 3.5 cents a foot), plus shipping. I ordered several other items, and the shipping charge for all was less than $10.00. You can see a photo on their web site, www.cabellas.com. Their part number is HB-51-1527. Much easier on my wife's eyes than baling-twine-orange!"

I only recently bought some of this, so I don't know how it will weather. It is strong enough to hold my weight (165 lb.)

We'll have to get you some heavier wire! :-)

Here's my story: I had a couple of 6 meter dipoles up. The only way
I can get them up here is with a slingshot or arrow through the trees,
so there are no pulleys. I used the 3/16" dacron. Naturally, the tree
branches eventually grew around the ropes - not a good thing. Well,
in my "infinite wisdom" I figured I'd use bigger rope so the branches
wouldn't grow around them. I spent almost $200 on *fat* non-dacron
rope at Home Depot, and a lot of time with the slingshot, until I could
haul that stuff up where I wanted it. The rope is 3/4". Got it up. The
damn stuff could probably support an elephant. It lasted through one
season, the branches welded them selves to it and the antennas broke.

So much for my "infinite wisdom". :-(

From: no@one.one
Message-ID: <9qfgelna1@news1.xs4all.nl>
Source record: 155972

Hi,

I'm in the process of building 2 helical antennas for AO40 operation:
70 cm en 13 cm band.
I'm using 2 (fairly old) programs:
- Helical-O-Matic 0.02 by N2VNO (windows)
- Helix 2.0 by OH0NC (dos)

Both programs will not process frequencies above 2.4 Ghz and I cannot
"play" enough with the parameters to find an optimum.
After reading the article "The Gain of the Axial-Mode Helix Antenna"
(http://www.tuc.nrao.edu/~demerson/helixgain/helix.htm) I also get the
impression that the programs are (obviously) fairly old and maybe not
completely up-to-date with the latest knowledge about helical antennas.

Are there any recent (freeware) design tools specifically for helical
antennas?

Thanks,

73, Andre PE1OIG

Well, so would I. :)

> code requires at least one supplemental electrode, so if you want

In the 1999 code it requires one additional ground rod IF the first
ground rod has more than 25ohms impedance to ground. It does not
require more than one to be added, even if adding the second does
not reduce the impedance below 25 ohms. In practice some people
will put in two electrodes rather than test (it is cheaper in most
cases) but I find more people use UFER or similar rather than a
ground rod.

> the electrical code.

Well... Maybe that is what your elec-inspector says. The code
itself says otherwise and of course every jurisdiction is free to
adopt the code or not in however manner they find appropriate. In
my experience a qualified engineer trumps code every time.

> Nope. We're talking a ham radio setup in the building. You cannot
> supply that equipment on a 200 amp branch circuit. Going further,

That's true. 1500w PEP just doesn't require 200 amps.

> assume the outbuilding houses a 200 amp load, and no ham equipment.
> You still can't have a single 200 amp branch. Single is the important

Yes you can.

> one additional "branch". And you have never seen a 200 amp
> branch circuit in a residential installation - it doesn't apply here at all.

Yes I have. (It was a home based business, the home had a 600amp
capacity.) I don't remember if the branch circuit fed the walk in
enviromental stress chamber, the crucible or the kiln.

> In addition, you may not split a branch circuit via a sub panel.
> By definition, it will no longer be a branch circuit. A branch circuit

That's correct. Do you ever do retrofit work? E.g. installing a
sub-panel converts the branch circuit to a feeder without running
new wires.

>> > supplied by a feeder, would have to have a sub-panel,
>>
>> Only if necessary to split the 200amp branch circuit.
>
> Please. The 200 amp branch circuit is fiction and not splitable.

If a facility is wired with a 200amp branch circuit and you desire
to split that branch circuit you would install a sub-panel.
Otherwise there is no need.

> building.

Right. That is silent on telling you what you "should" do, only
what you are not required to do. Creating the NEC is a very
political task, and politics often outweighs minor concerns. "You
are not required to add a grounding electrode" means just what it
says. It does not forbid and it does not require. So in the
interests of the safest job, what do you do?

...
> See 250-50 & 52 for part C.

No doubt. (I should probably look this up, but I don't have my book handy.) Re. the discussion of bonding neutral and ground at the sub-panel in the remote location, does part C require the added electrode in both cases? In practice adding the electrode is all I have done, because I feel it is easier and cheaper and probably more safe than the long, large grounding conductor otherwise required. (See the wire sizing for grounding conductors and made electrodes and bonding electrodes). But maybe this is the current requirement.

Ouch. Seems like wiring in another outlet or plugging in a
multi-outlet adaptor would have been the preferred approach...

I bought a large spool of weed-eater line from WalMart. I don't
remember the gauge, but it's about an eighth inch diameter. It
stretches some at first but it's been up for at least three years now.
When the wind blows it slides through the branches without fraying. I
think it works pretty good.

I have revised the Ladder Line Page on my home page. Follow the link at:

http://users.triconet.org/wesandlinda/

I now include some further discussion on how the data presented were determined and also include some revised values for the parameters of "Wireman" type '450' Ohm lines.

This is an ongoing revision and I hope to add excerpts from a reference or two that discuss radiation losses in balanced lines.

I've used some of this outside for over two years, and I can't detect any change whatever. It is not a single cord rather is a sheath over a core cord. Very good stuff and very strong. I highly recommend it, over the black polyester that I also use (although it is also very good, just not as good). I dodn't know what the tensile strength is but it surely is high. After all, they drop army tanks out of transport planes with 'chutes supported by numerous strands of it.

I decided to make a double bazooka antenna for 3.7mhz, testing the finished item I used my MFJ-259 and found the antenna resonates on 2.4 mhz.

The only difference was that I used RG58 CellFoam coax, the makers (RF Industries) spec say that is has a 76% VF, (and now I doubt this) which I used in the calculation.

My question is that as I understand it I can use my MFJ analyser to find out the true VF of the coax, I have a small piece left over.
When I test the coax do I terminate the end of the coax with a 50 ohm resistor, shorted or open ended?

I was curious about this answer since it didn't seem correct to me so I
downloaded the manual just to check it out.

The manual clearly states that: "The line can not be terminated in any impedance
other than an open or short."

Hi,

My new rig is on the way (ICOM 756PRO). Now I need to take care of an antenna.

My home is in a wooded area in West Central New Jersey near Clinton. Is there any experienced HAM in the area who would be willing to come take a look and offer his advice??

I was thinking of a small multi band beam to cover 10 thru 20 (Force12?)

Also some kind of vertical to handle 40 and 80?? NOt sure which would work in my situation.

Thanks,

Steve Silberman

692. Cushcraft X7 matching network problems

Source record: 155995

I am trying to get a Cushcraft X7 multi-element tryband yagi operational. Although this antenna assembles quite well, I am having problems that I've narrowed down to the balun.

For such a great antenna, the quality of their match box leaves much to be desired. The first one (that came with the antenna) was improperly assembled. Fortunately I discovered its problem with a visual inspection before I put the beam up on my tower.

Their replacement looked good (on visual inspection), but failed on the first day of operation. I've checked the coax cable and the driven element array, but have not yet gotten the balun down to dissect.

Has any other user had this sort of difficulty? What was done to rectify it? Would replacing it with a "real" balun such as the Centaur B41Y10-50 be a recommended fix?

TIA and 73, KB6CC

|1) I have seen two different versions of these--one with the loading
|coils at the feedpoint, and one with the coils in the middle (?) of
|each leg. Is either design better than the other?

Yes. If the loading is done at the feedpoint, less inductance is required, but the current through the loss resistance of the coil is higher. As the inductors are moved away from the feedpoint, more inductance is required but the current through the coil is reduced. Research has shown (I have an IEEE reference somewhere but can't lay my hands on it) that the "optimum" placement, assuming constant Q, is somewhere around the middle of the antenna.

|
|2) Does such an antenna have a chance of working okay mounted only 30
|feet above the ground?

"Okay" is in the eye of the beholder. It all depends on who you want to communicate with.

Rui Martins wrote:
"I`m from Portugal and I need to build an inexpensive antenna at home.
---I think they call it a dipole."

Muito Bem! We used to have an outstanding operator at the RARET Gloria Plant named Martins.

The dipole is a good choice in Portugal because the ground conductivity is not so good in many places. Of course along the margins of a river or the ocean you may be able to make good use of a vertical. Installation of a dipole array on a medium wave broadcast facility near Oporto is among my experiences in Portugal.

The length, 468 divided by the frequency in MHz, gives feet. It is already corrected for "end-effect" (shortened by about 5%). You can divide the number of feet by 3.28 for the total in meters.

Ideally a dipole to get distance through ionospheric propagation is elevated at least a half wavelength if possible.

Best regards, Richard Harrison, KB5WZI

Hi Duane,

I have the X9 since a few years which has probably the same balun as the X7. The 'only' problem I had with the balun matching was that 2 screws were not tightened inside the matchbox. After fixing this, all worked ok. However I have noticed a small crack in the balun kernel but sofar it has not affected the SWR performance.

hey steve
if you have a lot of trees and a big enough lot i would suggest a long wire antenna or a big loop strung between the trees
as for finding a ham in your area try going to www,.qrz,com and click on name seach and type in your zip code and it will give you a listing of all hams in your area and you can check them out and see if they have email then if they do email them also check on the same site for any clubs in your area and they may be able to help
good luck

I'm looking for an automatic antenna tuner (that can be installed remotely) that will tune a 120-foot dipole, fed with open wire feeders, to all ham bands from 160 through 10.

So far all of the automatic antenna tuners I've seen are for random single wire antennas.

Any suggestions?

Thanks...

708. Coaxial Zo and 138 Log(b/a) Formula

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-17 00:28:54 UTC
From: Jack Smith <jsmith@mnsinc.com>
Message-ID: <6uhpstcm6ua7fr62bi0p3dscavr3u67g2i@4ax.com>
Source record: 156011

After tinkering with measuring the Zo of zip cord, I thought I would write up a variety of cable characteristic measurement techniques. I identified about a dozen approaches to measuring Zo, Vf and attenuation and I started documenting them with actual examples for a typical coaxial and a sample balanced line.

One of the methods I tried, based on suggestions in rec.radio.amateur.antenna was a combination of physical measurements, electrical measurements and calculation. But, I'm getting inconsistent results. Here's the problem:

All data is for a 6.95 meters (22.80 feet) length of fresh Belden 8267 cable (RG-213).

The Belden web site provides the following physical specifications for 8267 cable:

Nominal Zo = 50 ohms
Nom Inductance = 0.077 uH/ft
Nom. Capacitance = 30.8 pF/ft
Nom. Vf = 0.66
Center conductor = 7 strands of 0.0296 dia Cu, = 0.089 inch nom
Dielectric solid polyethylene, diameter 0.285 inch.

I verified the nominal capacitance, with a measured value of 30.9 pF/ft.

The center conductor I measured with a digital micrometer as 0.0885 inch and the dielectric diameter as 0.287 inches. So, Belden's dimensions are confirmed reasonably closely.

The widely published high frequency Zo of coaxial cable is given by the formula:

Zo = [138 Log(D/d)] / Sqrt(Er) where:
D = inner diameter of shield = poly diameter = 0.285 inch
d = center conductor diameter = 0.089 inch
Er = dielectric constant of insulation, variously given for poly as 2.3, 2.27, and 2.26, with 2.3 being generally used.

When I plug Belden's numbers into the formula, I wind up with 46.0 ohms, not 50 ohms.

Further, the formula for the capacitance of a coaxial cylinder is:

C = [7.345 x Er] / Log(D/d) in pF/ft.

Using Belden's physical parameters, I calculated C as 33.65 pF/ft, which does not match either the published 30.8 pF/ft or my measured 30.9 pF/ft.

When I measured the actual cable Zo, using the methods I regard as most accurate with my test equipment, I see values ranging between 49.5 ohms and 50.6 ohms.

By the way, if you use the Zo = Sqrt(L/C) approach and use Belden's published L and C values, you get 50.0 ohms. This leads me to wonder whether Belden's published L is just a calculated value derived from the nominal Zo and C.

Terman's Radio Engineers Handbook (1943), provides the following formula for *low frequency* inductance of a coaxial cylinder:

L = 0.140 * log(D/d) + 0.015 uH/ft.

This yields 0.0858 uH/ft. Using the calculated C (33.65 pF/ft) and this calculated L, and Zo = Sqrt(L/C) you get 50.5 ohms.

The HF inductance should be less than what Terman notes for "low frequency," as the flux does not penetrate the conductors as it does at low frequencies.

I made my cable measurements around 5 MHz, at which frequency the skin depthfor copper is just over 0.001 inch, which is small compared with either the center conductor or shield. Thus, the "low frequency" adjustments one needs to make to L to compensate for internal inductance are not significant.

So, what am I missing here? I did not expect to see 10% divergence between the 138 log(D/d) / Sqrt (Er) formula and the cable's physical parameters.

Hi Jack,

I would be more amazed if it didn't.

By your own numbers I see the spread from 46.0 to 50.6 where the one
significant outlier is drawn from a formula, not measured.

It's not really automatic, but Bliss makes a motorized version of their
balanced-wire tuner that you can tune remotely...

714. Cushcraft X7 beam adjustment

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-17 03:11:10 UTC
From: Duane Thompson <dst@rmhcn.org>
Message-ID: <Pine.SUN.3.96.1011016200940.23174B-100000@eskimo.com>
Source record: 156017

With reference to the tuning tube shorting strap:

The instruction and assembly manual for the Big Thunder X7 states that "adjusting this strap will not have a significant effect on the VSWR" of the antenna.

Just what does the adjustment of that strap do?

715. VSWR vs. reflected power ratio

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-17 03:40:13 UTC
From: mcd <mcdoody@ix.netcom.com>
Message-ID: <9qiv6n$s5$1@slb5.atl.mindspring.net>
Source record: 156018

Can anyone give me a concise, understandable explanation of what the differences in the use of VSWR, reflected power loss, reflected power ratio and reflection coefficient are? All four are related but are slightly different ... what is unique about the meaning of each?
Mike

716. Re: Automatic antenna tuner, open wire fed dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-17 03:55:41 UTC

Message-ID: <8k7z7.1013$M55.579128@news.uswest.net>
Source record: 156019

Even though it is designed for a "long wire", I am using a SGC-237 with coax and a G5RV dipole. It works fine. I just connected the coax shield to the case of the tuner. I'm sure that it would be happier with a BALUN, but I was in a hurry when I hooked it up, and when it worked fine off the bat, I just left it.

They are related through standard equations. Rho is the magnitude
of the reflection coefficient. P- is the reflected power.
P+ is the forward power.

Rho = sqrt(P-/P+) SWR = (1+Rho)/(1-Rho)

Mike, answering your question via email on this newsgroup would be ineffective and nothing more than a list of definitions. You need to hit the books and develop the background you need to understand the meaning of these terms and how the concepts are applied. I would suggest a recent edition of the ARRL Antenna Book as a comprehensive starting point.

If you have been reading this newsgroup for long, you will recall that a lot of detailed and sometimes heated discussion has taken place in these areas.

On the other hand, someone may feel inclined to take on the task and summarize these topics for you.

Jack, download programs COAXPAIR and COAXRATE from website below.
They can be used for cable design. They are suitable for the sort
of calculations you are making and will provide much more highly
accurate information about cable characteristics and performance.
Links electrical measurements to dimensions.

Download in a few seconds each. Not zipped up. Run immediately.
Simple data entry - results in milli-seconds. Spot inconsistencies
in measured data.

Mike, I have to agree with George. The best thing to do is go back to the book where you found the names. Cecil has started you off with some arithmetical relationships and indeed, if you are not numerically inclined you will not get much further.

It is a relatively simple subject but reading what is written on these walls is guaranteed to cause confusion and may handicap you for the rest of your life. Emotions are easily aroused. The difficulty experienced by reader-learners lies in distinguishing wheat from chaff.

In this modern age only three meters remain in the radio shack - the clock, the S-meter and the SWR meter. This results in an unwarranted focus of attention in their directions. While you are nattering cross-town to your radio buddies there's nothing else to do except gaze at the SWR needle hopping about the scale. Consequently SWR is often the sole topic of conversation.

On the website below there's a short article on what the usual SWR meter actually does. Its name is a misnomer. Then settle down for 1/2-hour with an elementary radio and transmission line text book at your local library to find what a standing wave actually is before trying to measure it.

ARRL and RSGB handbooks make good reading.

Well, I'm no cable engineer, but I think I have an answer as to why you calculate 46 ohms but measure 50.

The theoretical formula for coax assumes that the shield and the wire are smooth uniform cylinders and that the dielectric uniformly fills the space between them. But in any coax with a woven braid shield, that's not exactly the case. There are tiny air gaps between shield and dielectric, and the braid may have slightly more inductance than a cylinder.

Add to this the fact that the e of the poly is not measured, and there may be enough factors to get 46 ohms rather than 50.

Just an idea.

Is it in the neighborhood of 12' tall? If so it's a 5/8. Is it around 60"- then it's a 1/4 wavelength antenna. Either way, put a VSWR meter on it- or antenna analyzer, and start pruning.

Dale W4OP

Of course, there are additional considerations, like noise and time
of day. But in general, low dipoles on 160m are good for a few hundred
miles and well-designed verticals are good for DX. A low dipole has
primarily higher angles of radiation and a well-designed vertical has
primarily lower angles of radiation.

Cecil:

Your terminology needs a little attention. You say "...well designed vertical..." when you are really including the total installation and environment, which is much more of a pattern determiner than what radiator size, and other details of the physical vertical itself. Most newbie readers wouldn't think to include the radials and matching network system in a "...well designed vertical...", for example. This is a common communication problem, but unfortunately it tends to mislead the very category of people who need the information the most, the underinformed. I try to remember to use terminology like "antenna system", or include all the pertinent components where I can.

Just a thought :)

728. Re: Automatic antenna tuner, open wire fed dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-17 14:47:08 UTC
From: ehsjr@bellatlantic.net
Message-ID: <3BCD99F5.E8033682@bellatlantic.net>
Source record: 156031

If you can't find one, you could modify your setup
to use an autotuner designed for coax, and make the
tuner remote. There's an article in either 73 or QST
that describes how one ham made an LDG AT-11
autotuner remote - and brought the manual controls
for the tuner into his shack via fiber instead of wire.
You'd need a balun at the tuner end of the open wire
feeder. Might not be pretty, might not be the best
approach, but it is easily doable.

vtail@hotmail.com wrote:

From: ehsjr@bellatlantic.net
Message-ID: <3BCD9D30.64C95FF1@bellatlantic.net>
Source record: 156030

I'm not sure of the extent to which the following applies,
but I believe it is THE answer.
A number of years ago, Bill, WA2WEJ, built a phased array for
EME - and went nuts trying to get the proper length phasing
lines. He contacted the coax manufacturer and discovered
that the published nominal velocity factor could differ from
the actual velocity factor by as much as + or - 20 percent,
according to the manufacturer.

I believe that the other nominal specs on the cable can vary,
too. If so, your measurements and math may be within
whatever percentage variation applies to those specs.
Heck, if the 20 percent, plus or minus, applies to characteristic
impedance, the cable could be 40 to 60 ohms. I doubt the
variation is that much (+ or - 20%) on all the specs - VF is the
only one Bill asked about - but there has got to be some
range.

|write up a variety of cable characteristic measurement techniques. I
|identified about a dozen approaches to measuring Zo, Vf and
|attenuation and I started documenting them with actual examples for a
|typical coaxial and a sample balanced line.
|
|One of the methods I tried, based on suggestions in
|rec.radio.amateur.antenna was a combination of physical measurements,
|electrical measurements and calculation. But, I'm getting inconsistent
|results. Here's the problem:
|
|All data is for a 6.95 meters (22.80 feet) length of fresh Belden 8267
|cable (RG-213).
|
|The Belden web site provides the following physical specifications for
|8267 cable:
|
|Nominal Zo = 50 ohms
|Nom Inductance = 0.077 uH/ft
|Nom. Capacitance = 30.8 pF/ft
|Nom. Vf = 0.66
|Center conductor = 7 strands of 0.0296 dia Cu, = 0.089 inch nom
|Dielectric solid polyethylene, diameter 0.285 inch.
|
|I verified the nominal capacitance, with a measured value of 30.9
|pF/ft.
|
|The center conductor I measured with a digital micrometer as 0.0885
|inch and the dielectric diameter as 0.287 inches. So, Belden's
|dimensions are confirmed reasonably closely.
|
|The widely published high frequency Zo of coaxial cable is given by
|the formula:
|
|Zo = [138 Log(D/d)] / Sqrt(Er) where:
|D = inner diameter of shield = poly diameter = 0.285 inch
|d = center conductor diameter = 0.089 inch
|Er = dielectric constant of insulation, variously given for poly as
|2.3, 2.27, and 2.26, with 2.3 being generally used.

The formula 138.03 log(D/d) / sqrt(Er) assumes a lossless line with perfectly smooth conductors. You have neither. Your line has loss; therefore, the characteristic impedance is complex. If your measurements and/or calculations

do not or cannot account for this then they will be in error.

To quote one of the better references on the subject ("Handbook of Coaxial Measurements", published by General Radio):

"In a coaxial line with perfect conductors the currents would flow only in infinitely thin layers on the conductive surfaces and the field would stay in the dielectric space between the conductors. But when the conductivities are finite the current flow extends somewhat below the metal surfaces and the field penetrates a little into the metal. One effect of the field penetration is that the magnitude of Zc is slightly higher than the value that (the formula above) gives for an ideal line, somewhat as though the conductor separation had increased. Less easy to explain on simple physical grounds is the fact that conductor loss causes a slight phase lag of the electrical field behind the magnetic field. This gives rise to a small negative imaginary (capacitive) component in Zc. If the conductor surfaces are compact and smooth by comparison with dimensions on the order of the skin depth, the real and negative imaginary components of the increment in Zc are equal."

(Note that when they said "the magnitude of Zc" I believe they should have said, "the real part of Zc.")

|
|When I plug Belden's numbers into the formula, I wind up with 46.0
|ohms, not 50 ohms.
|
|Further, the formula for the capacitance of a coaxial cylinder is:
|
|C = [7.345 x Er] / Log(D/d) in pF/ft.
|
|Using Belden's physical parameters, I calculated C as 33.65 pF/ft,
|which does not match either the published 30.8 pF/ft or my measured
|30.9 pF/ft.

A seven strand conductor with a nominal diameter 0.089" in not the same effective diameter as a smooth-solid wire of the same diameter. Likewise, the braid.

|
|When I measured the actual cable Zo, using the methods I regard as
|most accurate with my test equipment, I see values ranging between
|49.5 ohms and 50.6 ohms.

What more could you ask for?
|
|By the way, if you use the Zo = Sqrt(L/C) approach and use Belden's
|published L and C values, you get 50.0 ohms. This leads me to wonder
|whether Belden's published L is just a calculated value derived from
|the nominal Zo and C.

Probably. Measuring the inductance is not a trivial task, or for that matter is the measurement of a distributed capacitor at 5 MHz.

Although I am currently using a balanced tuner, I used an automatic long wire tuner to feed my balanced antenna for 3 years., Grounded the ground side of the tuner, then hooked the feed line to the ground and the hot. I was using the Alinco EDX-2. I added a few ferrite beads to the control line and the coax, but I would have done that whether it was end fed or balanced.

Depending on what tuner (really a "coupler") you have, will determine if you can match the 120 foot dipole on 160. Tuners and couplers are not magic. They have limits and you need to stay within them. Say you have an SGC230 coupler. It will match quite a lot of different impedance and maybe even a 120 foot dipole fed with 450 ohm ladder line on 160, but what is the coupler seeing as the load? Hook one side of the ladder line to each terminal on the coupler. No balun or unun is needed. The trick is to get the ladder line length NOT to be an odd multiple of a quarter wave length on the band you want to operate on. 100 feet seems to be a good length on all ham bands. However, the 120 foot dipole is short for 160 meters. Cut if for the bottom of 80 meters to work the whole 80 meter band on up to 10 meters. You should cut your dipole length to be a half wave long on the LOWEST band you want to operate on. Don't even try it with a coax fed dipole! In your case, you would need about a 250 foot total length dipole. An alternative method to get on 160 with your 120 dipole is to short the coupler end of the 450 ohm ladder line and operated the antenna as a T Marconi style over a good counterpoise. You could also simply disconnect the "ground" side of the ladder line and work the antenna as an inverted L over a good counterpoise. I would not bother trying with auto tuners such as an Icom AT180. It might work on the dipole if you are using a remote balun such as a W9INN, however, I have not tried this and the AT180 is not made to do this with a balance antenna fed with balanced line.

No problem. Antennas scale. Design the antenna for one tenth the actual frequency then reduce the physical dimensions of the actual antenna by the same scale factor of ten for use in the cm-band you want to use.

The best three complex measurements that I made are:
Freq (MHz) Z (ohms) Theta (degrees)
3.56 50.5 -0.70
10.68 50.5 -0.63
17.80 51.1 -0.60
>

Snipped excellent quotation

I've also seen this referenced in "Electronic Measurements" by Terman
and Pettit (1952). I'll see if my library can track it down on
inter-library loan.

>
>Probably. Measuring the inductance is not a trivial task, or for that matter is
>the measurement of a distributed capacitor at 5 MHz.

Terman and Pettit suggest a couple approaches to this, including using
a Q-meter at a frequency where the length of the line is much less
than a quarter wavelength. I'll give that another look. I've found
measuring the inductance at 1 KHz (also suggested by Terman and
Pettit) to be very difficult with a standard RLC universal bridge.

The term apparently favored is "internal inductance" and "external
inductance," with the external inductance (Le) being due to flux
between the inner and outer conductors and internal inductance being
due to flux within the center conductor (Li1) and outer conductor
(Li2). I've found an expression that distinguishes amongst Le, Li1 and
Li2, but not one that considers the frequency dependent effects of the
internal inductance.

What surprised me is that applying the standard 138 log (D/d) formula
gave results that were 10% in error, due to an aggregation of the
factors you mention.

The calculations are fairly easy, but if you want to try out different
values for different parameters (diameter, turn space etc.) to see what
happens that's a lot of work, so a computer program which allows you
to do that fairly easy sure helps a lot.
I already started programming something myself, but I found a program
which allows me to do what I want.
Take a look at http://users.bigpond.net.au/jhecker/HelixCalc.zip

Andre.

737. Need Help With Static Problem

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-17 23:19:53 UTC
From: Murray Green <mgreen@erols.com>
Message-ID: <3BCE2028.D3DA4908@erols.com>
Source record: 156039

Ok Antenna sleuths, here is a problem worthy of Sherlock Holmes.

Two commercial Cell Wave 4 element vertical dipole antennas went up about 5 years ago; one each for our club repeaters. Both fed with hard line, up on top of towers at about 80' above ground, and are identical.

About a year or so ago, on one of the repeaters, we began to hear static on windy days, BUT only on weak to moderate signals. (The other repeater experienced no static at all.) Strong signals over-ride the static. Also the static is not present when the repeater transmits special club announcements or IDs. So it appears to be an input problem.

The repeater and controller have been totally checked out including the duplexer. The hardline has been thoroughly grounded in three different places along it's length with copper braiding and coax grounding straps. Also the hardline connector to the base of the antenna was unwrapped and it was absolutely clean after 5 years; so clean that the word Amphanol could be seen imbedded on the inside of the tape. Coating solution was used on all taped parts. Absolutely impenetrable

During the above grounding process on a calm day, I asked one of the club tech types (who was at the top of the tower) to grab the support mast and shake it as a weak signal was inputted to the repeater. Sure enough, static was heard.

It is planned to climb the tower and take the antenna off it's mast and check it totally for any lose connections.

So what is my point? (1) If it is static created by a "loose connection", I would suspect that it should be heard regardless of whether the signal is from an input or the controller's output source and (2) should apply to all incoming signals not just the weaker ones.

"Wind static inherent in the antenna"? Why did it not show up the first 4 years; why isn't the other antenna affected? Also the preceding para applies.

Although we plan to pull the antenna off and check it, I would appreciate your comments. Thanks.

You DO understand about towers GENERATING noise as they are shook right?

Interesting voltaic connections between the bolts, etc.

And then there is the tower acting as an antenna for MANY different EM
waves.
(Conducting currents...)

Try Disconnecting the antenna from the tower with a broom handle or such.
(Temporarily replace the mast with a NON conductor.)

Murry Green wrote:
"Sure enough, static was heard."

Agitation produced static indicates a loose connection or unintentional intermittent short-circuit. It is occurring in the repeater exhibiting the problem and not occurring in the repeater not exhibiting the problem.

If you truely have two identical antenna systems you could swap them between repeaters to prove the problem moves with the antenna system.

The static must appear in the repeater receiver output since it does not appear on your club announcements. There is a lot of amplification in the receiver following the antenna system disturbance and no amplification following the transmit signal on the antenna until the signal arrives at the distant receiver. Just why the receiver limiters react differently on the opposite ends of this circuit, I don`t know. Do you have a static discharge problem in addition to a loose connection or short? Is the repeater receiver improperly tuned so that amplitude variations are not ignored?

Best regards, Richard Harrison, KB5WZI

Rui wrote:
"I want to make a horizontal dipole antenna for 11 meters."

OK. 27 MHz is actually 11.11 meters. A dipole is resonant at about half that length or 5.55 meters, less about 5% for "end effect", or 5.27 meters.

It is broken in the middle by an insulator for centerfeeding with coax. Either 50 or 75-ohm coax will be OK. The ends also need to be supported with insulators. Each half of the dipole will be about 2.64 meters long.

This horizontal dipole should be supported above ground at an elevation of 5.55 meters or more.

The problem with a horizontal antenna is that it works poorly with nearby vertical antennas which vehicles must use. For that reason, nearly all land based 11-meter stations use vertical antennas.

No problem for this dipole. It can be rotated into the vertical position. Just try to take the feedline away horizontally from the vertical antenna for a good ways. Put this antenna just as high as you can.

This antenna is so small that almost any hardware you can find is OK.

With a vertical dipole almost exactly like this I was able to communicate with Midland, Texas (about 9000 miles) from Tierra del Fuego Argentina using 5-watts.
Com certeza!

Best regards, Richard Harrison, KB5WZI

This was on ALL bands. This afternoon I got the match box down for examination. On a close look I saw that all of the connections were bad, and one was completely open unless I wriggled it.

I redid all of the connections, but when I put abalanced load on it (two, 100 ohm carbon resisters in series) and checked it with an analyzer I found it was faulty. Adjusting the winding spacing helped a bit, but... I may have shortened a wire a slight bit too much in fixing their solder job, but I think the thing is simply low quality and faulty.

I would hate to think that they are trying to sabotage what can be a great antenna with a lousy match box.

I will call them in the morning to get ANOTHER replacement on the way (yes, they've already replaced the first one). However, I think I will get a Centaur 4:1 balun to actually use.

Your letter is a refreshing change from "what rope do I need to hold up a dipole" TU

I have had experience of other (non-RF) cables and the variation of extruded dimensions along the length of a 50 foot coil is quite large.
The answer lies in Beldens." nom " ; nominal , ie what it is called - or even what they set out to make it as - but not what it is. They cannot guarantee it will be so. I think you are trying to apply Lab. standards to a practical every-day product.

For my part I think the correlation is v. good. You might like to take a drum of cable and measure your constants with a length cut from each end and one from the middle. I would be interested to hear how much variation there is in dimensions and measured properties of two pieces 50 feet apart.

set up the formulae in a computer and run a few calcs varying each input dimension by a few per cent (one at a time).

It will take only a little extra pressure on your micrometer to make the polythene dia. record as a bit smaller (on hot days) and I would think this would easily change the computed answer from 46 ohm to 50 ohm.

(1) In any network with only one generator, changing the impedance in one mesh will change the currents flowing in all other meshes.

(2) Common mode volts and amps have standing waves just like other modes. Putting some sort of choke in the line will shift the common mode waves up or down the line. Whether current or volts increase or decrease depends on where the measurements are made.

==========

Cease wondering. As it is impossible to measure L or C at HF independently of each other, there is no alternative but to cook the books and calculate L and C values from the more simple and practical measurements of Zo and velocity.

This has another desirable effect - it stops customers complaining that Sqrt(L/C) does not equal Zo in the catalogue and so disagreeing with the well-known handbooks.

But the only reason anyone would wish to know L and C is to calculate Zo and velocity if those values were not already known.

Manufacturers do not publish uncertainty limits of stated cable characteristics. It might scare customers away. As things are, we can spend all day erecting the new antenna and then go to bed and sleep happy with the thought that the SWR is 1-to-1 whereas it may be nearer to 1.5.

Andrew, download program TOPHAT1 from website below. This covers a top hat of any number of radial wires or rods.

But for 160m and 80m some inductive loading is needed unless you can erect a 1/8-wave vertical.. So download programs HELICAL3, VERTLOAD and LOADCOIL

What do you think about the condition in my antenna system? With
common-mode current measured at the choke, the common-mode current
is minimum at antenna system resonance and rises on each side.

Of course it isn't always possible to define exactly where true ground
is due to varying soil conditions. I've seen low HF antennas perform
well beyond that which would be expected for high takeoff angle
conditions.

763. Mobile Antenna Help

Source record: 156066

Hello, I've just passed my Technician Class license, and want to install a Kenwood 2m 50 watt rig in my Ford 2000 Ranger. Having a dilemma with antenna choices and where to place. The truck is a 3 year lease deal, and thus, drilling holes for roof top mount is not acceptable, and am concerned with mag mounts scratching the paint on a vehicle that I'll turn back in. What about stake mounted antenna on the bed rails, either at the front or rear? I know this hurts the omnidirectional pattern (from what I've read), but would this be acceptable. Also, what about the ground plane, I've got a bed liner in the back of the truck. 90% of the use will be in a very large city (1,000,000 metro population), with good access to repeaters. The primary repeater would be about 20 miles line of site from my house. Can the stake mount be done reliably? With a 36" antenna, the antenna tip would be just above the roof of the cab. Or, would a lip mount on the drivers side of the hood be better? Either way, antenna tip would be just above the roof of the cab. Also, at 36", antenna would just scrape the bottom of the garage door when entereing, any longer antenna, and there would definitely be resistance.

Thanks for any help, I'm really new to this world, and I'm excited about the contacts I'll be able to make.

Regards,
Van

I drilled a hole and installed an NMO mount in the roof of my leased car and told them it was for a cell phone (put a different whip on) and won't charge for it. They didn't care. I use a quarter wave, put have a 5/8 wave for those times when I might be the few extra miles from the repeaters.

Have you confimred this with the dealer? Most of them won't care as
long as you tell them it's for a cell phone antenna, and agree to
either leave the antenna on (keep your ham antenna and get a cheap
cell phone one before you take it back) or remove the mount and plug
the hole.

An NMO mount can make a world of difference. A $30 Diamond 1/4 wave
dual-bander will fit in almost any garage with no problem, and will
perform quite acceptably on an NMO. My recommendation, though, would
be to also grab a 1/2 or 5/8 wave with an NMO fitting or an adapter,
in case you need the extra range at some point.

I don't have the articles but I do have the keyer and remember some of the information.

You can just wire external paddles in paralell with the internal paddles.

If the keyer won't key your rig, in the manual are directions to lower the forward bias of the keyer. I also did it a different way before I found the notes in the manual, when one of my rigs would not key off of the keyer. I have the information on both.

You can email me via the Arrl forwarding service

If you can't find black dacron, visit a boat chandler. They have a huge variety of uv resistant materials, also pulleys which don't allow the line to jump off.

From: Jeff Pierce <piercejhsd009@earthlink.net>
Message-ID: <3BCF4602.B4315A9C@earthlink.net>
Source record: 156073

I need/want to build a VHF/UHF digital swr meter along the lines of the one from LDG Electronics using a PIC. I the QST article from July '99 plus the reprint and manual on the LDG site there are no PCB layouts for the VHF/UHF sensor. I do not want to buy the LDG boards. Why spend $25+ when I already have a bunch of 1n34 diodes, etc. All I need is the PCB artwork.

So, where can I find, preferably on the net, to calculate the strip line dimensions.

The strip lines in the vhf/uhf sensor are your classic line connecting the SO-239s with a strip on either side running parallel with the 50 ohm resistor to ground and the 1n34A for rectifying the voltage, and the other side a ground plane.

Source record: 156078

i would not call this a static problem since you can generate it by shaking the tower, check the tower itself for loose or rusted connections. guy wire attachments are really bad for generating this type of noise. you may also have an internal loose connection in the antenna. if you can swap the antennas that could narrow it down to the antenna or the tower. otherwise you are in for a hunt that has kept other repeater operators busy for years.

noise only shows up on weak signals because strong ones are probably strong enough to capture the receiver even when the noise is present, a function of the fm detector. the noise wouldn't show on the recorded announces because they aren't coming in through the rx where you receive the noise.

There is a section in the ARRL ant handbook. Other books also also.
Also you could use eznec,etc to model the antennas for each band. I
can see problems using multi bands, but it still might work out pretty
well, if you can take below par performance on some bands. There are
many ways you could go, and you would have to consider the spacing in
WL for each band used. This is where the modeling would come in handy
as you can set the phase angle any way you want. You would have to
decide on what type pattern you need for 40m. uni or bi directional,
etc. A 1/4 WL spacing on 40m, would be a 1/2 WL on 20m. So could be
unidirectional on 40m, and bidirectional on 20m, which other bands
probably being able to do ok, such as 30m, and 17,15m. The modeling
will give a good idea what to expect for any one band. You could
diddle with the phasing on the certain band you were on to vary the
pattern. I usually prefer coax lines to adjust the phasing, but in a
multi band setup like that a L/C type phasing box might be handy to
simplify things. You don't need exact precision in a setup like that.
I've phased both verticals and parallel dipoles, and always had real
good results. I ran a pair of 5/8 GPs on 10m one time and they worked
real well. I would add coax lines to change direction. Had a bunch of
switches. There are many fine points to doing all this in detail in
the books. Myself, I usually just rig it up and go for it it. I don't
try for or expect exact precision on this lot. I haven't had one not
work yet. I had good F/B using phased horizontal dipoles on 40m. 15-20
db worth or so it seemed in the real world. Maybe 4-5 db gain???.
Almost the normal two element yagi's worth. MK

You could try thin magnet wire if it doesn't have to be real strong. A
friend of mine uses it for 80/40 meter dipoles in a deed restrict
area. It can break in high winds, but you can just tie it back
together like string and solder it, and you are back in biz. It's
about as invisible as you are going to get I think. MK

775. Re: Grounding 2 stations

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-18 23:05:22 UTC
From: ehsjr@bellatlantic.net
Message-ID: <3BCF5E18.14B31CD3@bellatlantic.net>
Source record: 156077

You've got a number of things wrong - an engineer never trumps
the code; a single 200 amp circuit to an outbuilding can't exist
as a branch circuit; the most common existing form of grounding
(via the underground metal water pipe) requires a supplemental
electrode per 1999 code regardless of ground resistance; the
treatment of the code as a design spec. I'm tired of this, which
is becoming an argument, not a discussion. I don't want to argue.
Single point grounding has been adequately covered; if your shed
has a 200 amp circuit, get a licensed electrician to inspect/verify/correct
the grounding. Adding a grounding electrode for a single branch
circuit to the outbuilding has been recommended. I don't think
we have anything left to do but argue about where we disagree,
and I don't want to do that. If you have specific points about
where we disagree, I'll be willing to correspond via E mail. Or
if there is something new you want to discuss, I'll do it here.
But I don't want to waste everybody's time with arguing.

776. Ref. My Message On Antenna Static

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-18 23:15:02 UTC
From: Murray Green <mgreen@erols.com>
Message-ID: <3BCF7086.27F162A0@erols.com>
Source record: 156079

I was going to reply to each message sent to me but only got two off before my computer crashed and lost the remainder. Thanks for all of your replies. To the gentleman who asked about the receiver, it was checked out completely by our Tech expert who is a pro. Also, no static discharge problems. On swapping the antennas; impractical since both sitting on top of tower tanks. Should have made that clear in my original messages as opposed to just stating "tower". Again thanks and will post a message to the newsgroup when we take down the antenna and hopefully isolate/correct the problem.

***Thanks David. I like the explanation on weak vs strong signals.
Makes sense and one of the replies I was specifically looking for......
It is a "water" tank. Unfortunately I should have stated that instead
of "tower". Mislead some of the people who replied. No guy wires
involved and swapping antennas impractical. Will just lay it down and
on top of the tank and take a looksee. 73, mgreen

snipped some good ideas.

I have a 500 ft reel of RG-58A, and I'll scan it with the TDR and see how much of a delta Zo I see throughout the length. Probably won't have a chance to do that for a few days though.

I don't want to hack it up, but I may be able to cut a piece off both ends for a physical comparison

I was poking around the internet and ran across a web page that discussed pulse measurements of coaxial cable:

http://sist.fnal.gov/archive/2000-topics/Owusu/owusu.html

What I found interesting were the dimensions (in inches) for two types of Tines coaxial cable, nominal Zo = 50 ohms:

Cable No. Center OD Shield ID
AA-5966 0.26 0.91
AA-8740 0.380 1.340

Dielectric is polyethylene in both cases.

When I calculate Zo using 138 Log (D/d) / Sqrt Er, I get almost exactly 50 ohms. Using Er = 2.26 for poly:

AA-5966: Zo = 49.94 ohms
AA-8740: Zo = 50.24 ohms

So, here we have two examples of coaxial cable that match the classic formula within a fraction of one percent.

The two major differences between these two types of cables and the RG-213 that I measured are:

(a) stranded center in RG-213 vice solid in AA-5966 or tubular in AA-8740
(b) stranded braid in RG-213 vice AL foil with outer copper braid in AA-5966. (not described for AA-8740).

In all cases, the dielectric is poly, so the differences look to be associated with stranding, both of the center conductor and the braid.

I also ran across a comment in the classic MIT Radiation Laboratory series stating that coaxial cable manufacturers were delivering a product within +/- 2 ohms of nominal Zo during WW II. Whether we have

improved the manufacturing tolerance of mundane products such as coaxial cable since then is another interesting question.

One of the insulations available on Belden magnet wires used to be a bluish-green color, which is about as close to sky color as you can hope for.

Murray:
Those of us associated with the two-way industry recognize those symptoms immediately as a broken solder joint inside the antenna harness. Since the system is all DC continuous, it is much easier to completely disconnect the harness to locate the intermittent and repair it. DB harnesses had a bad run in the 70s, and I repaired a lot of them. Sinclair, Celwave, all of them have problems. If it is possible to restrain the top of the mast, this helps, but eventually all of them have problems. Be prepared to buy some expensive epoxy to repot the joint after repair, or it will not withstand weather afterwards.

If you can find an old HyGain 18AVT, it works well, however, elevating it will reduce the number of radials you need. Even at 8-10 feet you can get by with 4-6 radials/band (use rotator cable).

Good luck,

Bill, W4WNT

Duane,

Just bought one of these for myself... Haven't even opened the box yet.

Would be very interested and grateful if you'd keep me up to date on yours and how it's going.

Which other balun did you say you were thinking of using? Not sure I have heard of this other brand before.

Thanks & 73,

Mark

P.S. - if RESPONDING to this email, please remove the 'NOSPEM' . Thanks.

I have a flat roof where I am not supposed to put an antenna, but I can get away with putting up a Butternut HF5B:
http://www.noard.com/Butternut-HF5B.htm

Which location is the lesser of two evils? There is a TV antenna mounted on a mast. It looks like a horizontal yagi, but it's fixed, i.e., does not rotate.

1) On top of a mast that's fastened to the existing TV antenna mast (so it really is like an extension of the TV mast), so that my antenna is directly above the TV antenna by about four feet. Anybody know what deleterious effects the juxtaposition of these two antennas might have? (Sorry for all the big words.)

2) On a mast so that it's about 20 feet away from the existing TV antenna, but about 6 feet higher. Intuitively this sounds better, but RF propagation is not a trivial subject. My beam will often point toward the TV antenna from this position. Also, the coaxial feed line will be about 20 feet longer.

Don't hesitate to proffer any opinions on this antenna, or any other small beam you know of.

792. Problem in short range digital transmission using 315Mhz

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-19 04:43:43 UTC
From: kkzh@hotmail.com
Message-ID: <e317eb65.0110182043.3438a7b2@posting.google.com>
Source record: 156095
Cross-posted to: alt.ham-radio.vhf-uhf,rec.radio.amateur.antenna,alt.ham-radio.packet,alt.radio.digital,alt.radio.uk

We have to transmit digital data at 2400bps via AM at 315Mhz between vehicles and a data centre within the depot area (150 meters in diameter)in half duplex mode. We are now using 1/4 wave length monopoles at both ends. Our transcievers are working at 50mW low power level owing to restriction imposed by local law.

The following problem was discovered:
The performance of the radio link depends very much on the position of the antenna on top the vehicle. If the antenna is mounted at the center of the roof of the vehicle's cabin, the error rate becomes very bad. If the antenna is mounted at the edge of the roof top (only at certain positions), the error rate is reduced. Measurement by field strength meter gives no difference among different positions of the antenna. This phenomina happen in all distances, say 30, 50, 80 meters.

Is there any solution for this problem under our present constriants?
What is the reason for this problem?

Best regards,
kk

The only thing I see in this scenario is the potential for TVI. The TV antenna really shouldn't affect the performance of the HF5B in either location...or vice-versa.
I don't think you could go any smaller with any "beam" and expect beam performance. If you are gonna suffer TVI complaints, might as well put up a bigger honker rather than smaller.
If it were me, I'd go for the latter location to where I could have a rotor, etc. The feedline distance loss is negligible.

First, did you check a full 360 degrees around the vehicle with the field strength meter? At 315 MHz you may have some null spots in the radiation pattern due to reflections from other parts of the vehicle. Also if you don't have nulls caused by reflections the radiation patter may still drop to a low value because the pattern is not symmetric, i.e. the field strength will be higher along the longer dimension of the metal body of the vehicle.

Second the antennas used on the vehicle, and at the data center, should both be vertical for general omnidirectional coverage, and way out in the clear away from other metal like that used for building walls, I-beams, etc.

Third, are you sure that only one transmitter is active at a time? I'm assuming that you are using a single frequency for all of the vehicles

Fourth, are all the transmitters etc. tuned to the same frequency?

Fifth, monitor the frequency to see if there is any other signal on the air which may interfere with the data transmission.

Sixth, have you tried to change the modulation level of the data transmitters? You maybe over, or under, modulating the transmitter.

Seventh, if you have any filters installed in the transmitters, and data receivers, are they the right frequency and bandwidth for your data rate?

These should help you to start looking in the right direction, and may even point out the problem to fix.

There may be something in respect to the antenna being used that is
heavily dependent on the ground plane of the vehicle. The more
successful (predictable) antennas at such freqs tend to be colinear type
schemes that don't give a hoot about the metal below. Given your
experiences, I wouldn't rely on a simple 1/4 or 5/8 wave antenna.

Hi Jack,

You may want to reappraise this statement about "classic" especially
when the equation undoubtedly comes from an era when 50 Ohm cable was
specified at 51.5 Ohms. I can recall many non-50 Ohm nominal values
(all close to 50 Ohms however) that I calibrated instruments to. The
ME-11 wattmeter and load is a specific example.

Hello,

There is a legal, license free, experimenter band from (I think) 150 to
200 Khz. The "rules" are that the input power to the antenna can be no
more than 1 watt and the vertical antenna and feedline be no more than
50 feet.

I got this from one web page:

Unlicensed experimenters--some of them hams--currently operate on LF in
the US under the FCC's Part 15 rules. These limit transmitter input
power to 1 W and impose substantial restrictions on the size of the
antenna. The proposed allocations "will provide the only low-frequency
allocation for amateur use and will accommodate more flexible
experimentation than is permitted under current Part 15 regulations,"
the League's filing said.

and this from another:

In the USA operation is allowed between 160-190kHz under FCC Part 15
conditions (less than 1W DC input to antennas not longer than 50 feet).
Results have been remarkable.

And these links about "Lo'fers":

http://www.anarc.org/lwca/aboutlw.html
http://www.altair.org/lowfer.htm
http://www.cpinternet.com/~lyle/lftx.htm
http://www.cpinternet.com/~lyle/models/lftxant.htm
http://www.provcomm.net/pages/joe/lowfer.htm

AND MANY OTHERS

The facts are, my homebrew radio club is building tube type transmitters for a contest that we are having. It doesn't matter what frequency band or mode of transmission that we use - as long as we use tubes in the design. I have a 160 Khz crystal and I'm going to build it on an old radio chassis. I don't want to get into parasitic oscillations and stuff that you get from HF and VHF stuff (i.e. - the higher you go, the more you had better know about it). I've built some tube type audio stuff and I'd think that the techniques couldn't be terribly much different at such a low frequency (except that basic RF considerations must be in place). I have the tube (12AX7) and the crystal and points are given for reusing old "junque" so this is what I plan to build. I think that we're testing into a dummy load but it would be nice to get it on the air for at least a few minutes before I scrap it.

That's the basic idea. Not really for communications - just for fun.

Thanks for the reply.

Paul

Hi OM,

If you trust your Field Strength measurements, you have to distrust your antenna placement correlation to better data transfer. These two reports conflict at a fundamental level. That is to say, your problem does not seem to be one of signal strength. Given your application is digital data at UHF, it would be reasonable to assume that perhaps multipath is causing the bits to be lost.

Multipath is a situation where the receiver hears two identical signals slightly shifted in time because they arrived at the antenna different times - this is especially significant at short wavelengths (and your 1 Meter wavelength qualifies). The simplest common example are ghosts on TV (but in the era of cable, our children will never know how we "roughed it" in the old days). These delayed identical signals are reflections.

Life is full of reflections, especially your workplace. However the designers of your system were aware of that and slowed the bit rate to 2400 BAUD which should be sufficient. Even the ghosts on TV are far weaker signals than the primary picture (and sometimes it is the

reflection that is stronger than the "direct" signal)). In such environments you suffer from what is called the fresnel zone where the combination of all reflections yield a radio shadow. This is simply multipath in the extreme and the most common form of experiencing it for voice communications, is the signal comes and goes periodically in a form we call "picket fencing" as the receiver (or transmitter) moves.

By now you should be able to recognize this is a geometric based problem, not antenna or radio per sï¿½. One method to combat these kind of problems is through using diversity reception. The simplest form is to use multiple antennas spaced roughly 1/4 M apart in your case but combined at the receiver. The logic here is that one antenna may be in trouble, but its neighbor 1/4 wavelength away is bound to be in a better position.

Hi Paul,

Sounds neat and you are certainly covered as far as the law goes.
However, unless you make a contact, it sounds worse than academic.
Who's to say what you've built if no one can tell if it works?

So to the matters we love to discuss. Antennas being one, we must all
observe that even at 500 feet, an antenna THAT long would still seem
to be a short circuit (OK, as distinct from a 50 foot absolute short
circuit). For me, I would have designed the transmitter to the
antenna and chosen to go solid state and perform some DC-DC
conversions for 90+% efficiency into that same short (building a 90%
effective short is another matter).

So when I read of your contest restriction to tubes - that seemed to
go by-the-by. As the tube is a Hi-Z device, it's application to a

Lo-Z load seems to portend problems, but then I have to reflect that this is nearly audio and transformers work efficently to this issue quite well.

Have Fun.

Source record: 156105

I have a friend who has DXCC on basically every band with the exception of 80 meters. He works primarily CW. Unfortunately he lives on a small lot and doesn't have much room for more elaborate antennas. Could some of you who work 80 meter DX and 5BDXCC offer some suggestions on what works for you in the antenna department - particularly those of you that are spatially challenged.

If you happen to encounter a posting about a particular antenna that you personally had a bad experience with I would like to hear about that as well.

Thank you all for your time and comments.
if you are aware of a place where this may receive other good comments please repost it and let me know of the site so I can subscribe and watch the responses.

Cecil asked -
> What do you think about the condition in my antenna system? With
> common-mode current measured at the choke, the common-mode
current
> is minimum at antenna system resonance and rises on each side.
==========
I'm not surprised. Keeping it simple - if at antenna resonance
maximum current flows in the antenna then there's less current to
flow in the common mode - assuming transmitter power output stays
in the same ball park.

Inserting a choke and readjusting the tuner merely changes the
directional properties of the system. Exactly the same total power
is radiated

Inserting a choke in the feedline does not necessarily prevent
radiation from the feedline. It is just as likely to increase it.
The choke changes the coupling mode between antenna and feeder.
The phase relationships change as in any other multi-element
system.

But if inserting the choke prevents lips being burned by the
microphone then everybody is happy and the feedline can carry on
radiating as much as it likes.

I doubt you'll be able to make much of a determination. Because of the cable loss, what you'll see is a step that rises with time, heading for its open circuit value. You'll be able to see relatively abrupt changes in the cable, like spots where it's distorted or crushed, but slow trends are hard to dig out of the waveform. I think some of the newer TDRs have software to do this, but I haven't seen them to say for sure.

KK wrote:
"The performance of the radio link depends very much on the position of the antenna on the top of the vehicle."

315 MHz is a line-of-sight frequency. Range required is 75 meters? The size of the depot is given as 150 meters in diameter.

50 milliwatts is +17 dbm. Space loss at 315 MHz over a distance of 75 meters is about 55 db. Ample signal should be available over a clear path.

A problem may arise from destructive interference of a reflection from a nearby object or structure. A wavelength is near one meter, so not much size is needed to make a big reflection.

With high power, the same problem may arise, but not so often because the remnant power is more often sufficient. FM helps overcome destructive interference because if you have enough signal to put the receiver into limiting, there is very little change in amplitude of signal output regardless of the strength of the r-f received.

Use FM. Put the base antenna up where it is visible from all remote locations, and your system will likely have a good chance of working.

Best regards, Richard Harrison, KB5WZI

Richard Clark wrote:
"One method to combat these kinds of problems is through diversity reception."

Very true, but space diversity is far too complicated for most users. Multiple antennas spaced at some distance is not enough. These are merely phased arrays, and they will totally cancel at some signal combination.

A complicated signal combiner (selector) which decides which is the antenna producing the best signal is an absolute necessity to make space diversity work. Nearly always this means each antenna feeds its own receiver and the best received signal is picked from the receiver outputs. The best is selected and the others are rejected by an electronic process.

Best regards, Richard Harrison, KB5WZI

Fair enough! I live on about 2 acres. Most of it heavy woods.
House is two story with Shack on second floor. At one end of the
house there is an old TV antenna which I was thinking of replacing
with a small beam to cover 10 thru 20 meters. Its the opposite end
of the house from the Shack which would make the feed line about 70
feet or so. Also the Electric and Cable TV come into the house at
that end and would be below the beam and slightly off to one side.

On the other end of the house there is a high chimney. THis is very
close to a large Oak tree so I'm not sure what use I can make of it.

One other thought was to run some kind of Wire antenna into the woods
(through clear spaces). I would want to use this for 40 and 80
Meters.

I currently have a RF Systems MarkII Sloper into the woods which is a
listen only type antenna for SWL.

Any comments are appreciated.

Small lot - 80 meters - DX

Almost a complete prescription for a vertical antenna system.

Your friend can buy the Butternut HF2V for 80 and 40 and have an excellent non-trap two-band antenna, or make a vertical easily from aluminum tubing. Texas Towers in Plano, TX carries all sizes of tubing that telescope and are available in 6 ft lengths for UPS shipping.

The key, of course, is to lay out the very best radial field possible. I strongly suggest ground mounting for 80 and 40. As many radials of about 0.2 wavelength (actual lengths are not critical with ground radials) as can be installed.

If he goes the homemade route, top-loading with guy wires, etc. will be more power efficient that loading coils.

He should expect narrow SWR bandwidths with any efficient vertical on 80, so he might plan to use a tuner to cover portions of the band outside the "sweet spot."

Any type of horizontal antenna would have to be mounted at least 1/2-wavelength high to obtain much low-angle radiation for DX work, and placing an antenna, even a shortened one, 130 feet in the air on a small lot is a tough job.

Juan M wrote:
"Any recommendations for a ground-mounted 80-10 meter vertical?"

Sure, if you are interested in one sense, N-S, E-W, etc at a time.

It only takes one support pole and a length of wire spanning the top of the pole and headed toward the ground on opposite sides of the pole. This is called a vertical half-rhombic. A counterpoise is often run near ground level under the overhead wire. It may not be difficult to move the ends of the wires around to change the preferred directions of the antenna. The antenna works best in the directions that the wires are pointed for their horizontal component.

A 400-ohm termination resistor is often used between the far ends of the antenna wire and its counterpoise beneath. This makes the antenna unidirectional toward the resistor.

This antenna will present a fairly constant impedance over the entire frequency range but the radiation take-off angle comes down and horizontal beamwidth narrows as the frequency goes up.

The antenna works best with a certain wire length for a certain frequency. The War Department gives a formula:

L = Hsquared (F)/730 + 183/F
L = optimum leg length in feet (there are two legs)
H = pole height in feet
F = frequency in MHz

The War Department gives a table for gain at 30 MHz. With a 50-ft pole, and leg lengths of 109 ft ea, gain over a half-wave vertical dipole of the elevation of the apex, is 0-8 db depending on ground conductivity.

This antenna accepts a wide frequency range and beats a dummy load by a bunch.

Best regards, Richard Harrison, KB5WZI

Greetings,

Reading Bill Orr's book on Verticals I catch a lot of good ideas.
One thing though: Both in his book and elsewhere I notice that no
matter how detailed the instructions (length, dia., turns,etc.)
no one ever says how to KEEP the coils on the PVC or whatever.
I've done several homebrew wire antennas -- that wire is not just
gonna lay there all neatly coiled while you fiddle about reading
the uH or whatever. And gooping sealant all over it won't be too
helpful when it turns out you need to rewind a turn or two either
plus or minus. Can anyone help with *practical*, not theory,
tips on coil construction ??? Thanks,

Hi Stephen,

Use standard house wire and toss it over the canopy of your trees - or
if you have the luxury (I don't) fit it into those clear spaces.
Build yourself a good ground where it drops down. "Good" being quite
variable in estimation, and "ground" being highly emotional in this
venue - is another can of worms best left to a different thread ;-)

"Good" is the return on your effort for the first 10 dB you gained
over your first experimental antenna. 6 of that 10 dB probably came
from simply connecting a ground wire to set for the first time.

That's as "Good" as it gets (within 3 dB) until you are ready to pony
up big bucks for the next 10 dB gain.

Hi Andrew,

If you are speaking about closely wound coils, yes it can be a problem
(use insulated wire) but more the problem is that if you form windings
with less than a 2 or 3 wire diameter gap, you are adding loss.

With this much separation, it still requires a tight wind for the
spiral to not wander, but that doesn't matter a whole lot if over the
length of the coil you come to some suitable average and do not short
windings along the way. Keeping the wrap tight means stabilizing the
ends of the wire, I use hot glue.

This is like the old Ripley's Believe it or Not panel that suggested
if you took a rope that tightly wound the earth (no room beneath it to
put your finger) and added 2 Meters to its length (to the already 40
million there), it would suddenly have enough slack everywhere to be
lifted off the earth by nearly 1 Meter. Such is the effect of a 0.1
ppm change that make tight winds difficult.

Roy, I don't understand your question. I'll ask you one.

If measured values of L,C,R,G are inserted in -

Zo = Sqrt((R+jwL)/(G+jwC)

and measured Zo is not equal to calculated Zo, should the
discrepancy be attributed to the formula or to the measurements ?

Regards, Reg, G4FGQ

> Can anyone help with *practical*, not theory,
> tips on coil construction ??? Thanks,

One trick I use is to tightly wind the coil on something slightly smaller in diameter. Then carefully remove it from the smaller form and work it onto the larger form. Of course, you'll have to wrap a turn or two 'extra' on the smaller form to end up with the correct turns count on the larger form.

This trick is more practical with 'substantial' gauge wire used in 'practical' sized coils. It ain't what you want to use when you're making a gazillion-turn coil out of 30 ga. wire...

The best way is probably to spirally notch the coil form
on a lathe and then wind the wire under tension.

What I do is use thick wire with the insulation still on as a winding
spacer.
I drill holes in the ends of the forms. When I wind the coils, I tie a
small knot in the end of the wire, to pull tight against the hole on
the form. I wind the coil real tight against the form and when to the
other end I run the wire though the hole on the other end and tie
another small knot. These stay together with no glue or anything else
needed. I use at least #14 insulated wire when I make these. Some use
#12. So far have worked pretty well. I used two of these on a
shortened 160m dipole and did fine. The coils were over a foot long.
The only drawback to this method is the coils are pretty heavy. MK

Your vehicle roof is flexing. You are using a magmount? The capacity of the magmount/vehicle roof capacitor varies and modulates the signal sufficiently to corrupt the data.
At the edges the roof is stiffer.

electrically bond the antenna coax ground to vehicle metal. Better still use a vert. dipole and not rely on vehicle body at all.

I've got a 7' high fence across the back of my small lot (60'). Used to be a military installation, but now it's a park. I'm considering mounting an HF vertical to the top of a fence pole (1 1/2' heavy-duty galv. steel). I know that a good counterpoise is important for performance. Any thoughts on this installation? I suspect I'll need to bury some ground radials at right-angles to the fence. Will the fence have drastic effects on the radiation pattern of the antenna?

Source record: 155878

You have a loose metal-to-metal connection somplace in the
near field of the antenna radiation pattern. What is happening
is that enough transmitter RF is causing microscopic "arcing"
across those loose connections to cause broadband noise
which is failing on your repeater input.

The noise is AM in nature, and will easily pass the limiter
stages in your FM receiver, except on strong signals where
the "noise" is removed by the limiters.

Why are you looking at the duplexer or controller for a wind related
problem?

You don't hear the static on the repeater tail or DVR tracks
because the receiver is squelched during these intervals.
You may also find you repeater might be appear to be
slightly "deaf" on windy days since the static raises the noise
floor of the RX and also increases the squelch action.

You need to check the mechanical joints of the antenna, and
all coax fittings for tightness or corrosion; including all of
the diplole mounts and the mounting plate. You also need to
check all nearby metal objects that may be loose or rubbing.
That is where the problem will lay.

Have someone rub two screwdrivers together near one of
dipole elements when a weak signal is activating the repeater,
and you will see the mechanism for this problem. The problem
is also very common to certain fiberglas radome enclosed
commercial colinear antennas when used in repeater service--
after several years of flexing the internal elements develop
fatique points on the soldered connections and become
intermittent.

Best regards

Peter, K1ZJH

Rick,

1) Is it your fence or does it belong to the people behind you?

If you own it, or can otherwise get permission to use it, give it a try.

2) Does the fence extend beyond the 60' of your lot? You may not necessarily need any radials at all. Right angles are nice, but not absolutely necessary. There may be enough metal just in the fence alone to suffice.

3) What is the fence made of? Are there good metal-to-metal connections all around? if not, you could use "stealth" radials...just string them along the length of the fence, or interweave them within the fence.

I'd throw up the vertical and see what happens! You may be very pleasantly surprised!

Most of my coils have been close wound on toilet roll tubes, plastic aspirin bottles and 35mm film cartons, with close-wound 10 to 18-gauge wire. A dab of superglue or polystyrene dope holds things in place. For 160m helicals use 3" diameter plastic drain pipes. Anchor wire ends at a pair of holes spaced 1/2" apart drilled or melted in the coil former. For small VHF self-supporting coils wrap a few turns round a pencil and then slide off. Big coils can be wound with 3/8" diameter copper pipe and also be self-supporting. For spaced turns wind the wire in parallel with a length of cord or string.

You might try http://www.google.com

Enter various word combinations into the search engine. I tried "receiver antenna tuner circuit," "homebrew shortwave antenna tuner," etc., and came up with several urls.

By the way, ham transmitting tuners for the 160 thru 10 meter bands should also work fine for receiving shortwave below 32 mhz -- the only real difference is the ham tuners might be a little more rugged than a receive-only tuner.

Mayhaps somebody has a specific site -- there are probably books that cover this, available at sw radio suppliers...

Good luck,

Bob

Hi,

A lot depends on what you are trying to do. Two possibilities come to mind, but there are others.

The first one is to provide selectivity in front of a radio that has an overload problem. Back in the good old days this often was done with an outboard tuner. Most people do it differently these days. What you generally see in modern setups is a bank of narrow band RF filters that are switched in and out as required. The main cost in this kind of setup is the relays to do the switching. If you use some kind of plug in arrangement it can be pretty darn cheap.

The second possibility is to get more signal into the receiver. Unless you have a *very* short antenna or a *very* dead receiver this often does you more harm than good. If the noise coming out of the radio goes up when the antenna is attached then a better match won't do you any good. As a matter of fact any match that provides more signal in that case will cause you overload problems without any improvement in signal readability. Most simple modern radios and an awful lot of older ones will do very well with about 30 feet of wire for an antenna. Anything more than that may run you into overload issues.

All that said there are a number of places you can go for schematics. Almost any copy of the ARRL handbook will have several antenna tuners in it. They work every bit as well on receive as on transmit. I'm sure Reg is lurking in here somewhere and he has all kinds of neat software for designing a variety of simple tuners. I'll save him the bandwidth point you to : http://www.btinternet.com/~g4fgq.regp/ . I'm sure if you have any questions about them he will pop up to answer them.

Hope that helps rather than confuses.

Enjoy!

Is Fence wooden? Ignore it.

Is fence metal? join one side of feeder to it.

Are fence posts in concrete lumps ? Drive in one big ground rod to earth
the fence at antenna base and another a quarter wave away in each direction.

An insulated counterpoise is ok .
a thoroughly earthed one is ok .
but one which is earthed via 70 ohms -ish concrete is bad news.
Why warm concrete.?

tuner
> for a receiver below 32 MHz"
==========
Rex, you don't want an antenna tuner - you want a preselector. A preselector is designed to be much more selective than a transmitter antenna tuner. It will discriminate between unwanted powerful interfering transmissions and the weaker wanted signals.

An antenna tuner will put maximum signal strength into the receiver. At HF, signal strength is already more than enough for most receivers. Overload and distortion often occurs.

Reg.

Hi Tim,
someone has Already sugested the butternut, and I would stay away from the
Gap antenna on 80m it's a poor performer on that band. but another old time
favorite is the 1/2w inverted L. making the vertical portion as tall as
possible. It's worked well from me over the years and it's quite easy to
match at the base. put in the best radial system possible. Though the Half
wave antenna doesn't need as an extensive radial system as a 1/4. put in the
best you can.
also you may want to take a look at L.B's fine write up on this antenna at.

I wouldn't expect it to be too good. You still wouldn't have much in
the way of radials under the antenna. I know someone that tried doing
this with a gap vertical. It didn't work too well. Also a possible
problem is rf problems due to all the bad joints in the fence if chain
link. Lots of potential diodes. :(
But if you have no other choice I guess it would be better than
nothing. If you had a few tuned elevated radials per band it would
help greatly. You would be better off using the fence pole to hold a
taller mast pole, and hanging an all band dipole or inv vee. Even at
20 ft it would do pretty well. MK

842. Antennas that don't work

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-20 12:26:14 UTC
From: "David J. Windisch" <davidw@copper.net>
Message-ID: <34eA7.49$cQ1.68749@newsfeed.slurp.net>
Source record: 155895

I remember when all I knew about antennas that I was told don't work was that I could work the world on 80-40-20M c-w after I ignored well-meant advice, climbed to the top of that old tulip-poplar tree over there in the back yard, threw a length of wire out so it hit the ground, and ran it over the roof of the carport and in under a metal-flashed wooden window sill to my trusty 6AG7-807 and Hammarlund BC779 shack combo. I had to wait in line until W3BVN, K2DGT, W8FGX, W8JIN, K3GKF, W3JNN, and, it seemed, every other ham in the world had my turn in the pile-ups, but that's life when a kid gets out of his own back yard.

What's the point?

Well, if you can learn to see antennas through the eyes of a child, maybe you'll try something, and then try something else, and something else after that, and build up your own store of knowledge about how well things you try work .. and be convinced, I hope, that all things work; the difference is that some things work better than other things.

Don't just sit there -- get off your duff and try something. Persevere until the end. Begin with getting a good antenna tuner. Nowadays, I have a bunch of them, mostly homebrew tee- and pi-nets, and a couple of Johnson KW MatchBox-es as well.

Is that enough to start the "this tuner's better than that tuner" debate again?

Tune for maximum smoke.

Source record: 155899

It is difficult to recommend an antenna without knowing exactly
how much space is available. A quarter-wave inverted-L will
fit in a small garden. 10M high and 10M horizontal should
work fine. He would need a reasonably good ground to make it
work efficiently. Such an antenna will probably perform better
than an expensive ground-mounted vertical.

If he can't find room for an inverted-L, he might consider
a vertical or a magnetic loop.

Dear Roy, surely you can see that if you can answer my question
then you will be able to answer your own. (Which I still don't get
the point of). I repeat my simple unambiguous question -

"If measured values of L,C,R,G are inserted in -

Zo = Sqrt((R+jwL)/(G+jwC))

and measured Zo is not equal to calculated Zo, should the
discrepancy be attributed to the formula or to the measurements ?

Ah Punchinello,

Cutting baloney by the pound now? Both the standard preselector and antenna tuner consist of, at a minimum, two reactive components - notably a cap and coil. The combination of these into a useful circuit combine to provide the classic 6 dB per octave or 20 dB per decade roll-off to either side of a resonance.

The standard tuner generally consists of a third reactance, and as that could conceivable dismiss the accuracy of your statement (not that it hasn't been blown off already) we should not let these old wive's tales begin much less propagate.

I can anticipate some crusty homily about the high impedance of the front end of the receiver nonsense to artificially create a Q based argument. Such is the stuff of legend and make-believe to soothe worn out parents trotting out these tales to their children for bed-time.

Rex,

a tuner is perfectly suitable and the preselector (by definition) adds nothing to this but gain (if you want to hear more noise). The tuner is far easier to build for yourself, and far simpler to find, and far cheaper for equivalent parts. The circuit diagram you are looking for is one with switches to these two components that rearranges them into all possible combinations of series and parallel configurations situated between the goesinta and comesoutta.

}}} "this tuner's better than that tuner" {{{

Different tuner circuits are better for some applications than others. Matter of fact, some tuner circuits won't work at all with certain antenna types, without supplemental components (i.e., unbal tuner, bal ant, balun).

Then, we get into adequacy of component design values, as well as quality of construction. All these factors have to be addressed before we can even get close to saying "this tuner is better than that one".

Sure have to agree, too, on your theory of making do with what you have, in the way of yard, trees, space, etc. There well may be limitations and constraints, but most of us can't do anything about those, other than go buy another place. The thing to do is simply put up what you can and then use it.

850. K1FO dimensions

Newsgroup: rec.radio.amateur.antenna

Message-ID: <tt3o4na8v73j7a@corp.supernews.com>
Source record: 155903

Hello all,

Does anyone have the dimensions for the driven element and Tee-match for a K1FO style 2 meter yagi (centered on ~144.2MHz). I have built several K1FO style antennas for 432MHz so I'm familiar with how they are constructed. The handbooks I have include complete details for that band. They also show the boom, elements and spacing for 2 meters, but they do not show the driven element and Tee-match in detail. I have two antennas built with the exception of the driven elements. I could use the old cut-and-try method, but thought I'd look for someone who had already done it.

Thanks,

Gary - WY0V

Theory (formula) is never inaccurate, only incomplete.
Measurements are always inaccurate - but how much ?

Which foot is in front ? Left or right ?

Philosophically yours,

de VE1BLL@rac.ca

852. Off-Center Fed (OCF) Dipoles for 160-10, suggestions?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-20 22:23:23 UTC
From: vtail@hotmail.com
Message-ID: <3bd1eff5.28808940@news.netis.com>
Source record: 155905

I was reading in the ARRL Antenna Book about off-center-fed (OCF) dipoles, and it looks like such a dipole should fit right in around here.

I have enough space to put up a half wave dipole for 160 (about 250-260 feet or so). I'd like to be able to use that antenna for all bands 160 through 10.

I'll only be able to get it about 40 feet up in the air.

The shack is about a third of the way across the yard, hence my thoughts on the OCF antenna.

My options are:

1. Center fed dipole, open wire feeders. Feeders will not be able to run at right angles to the antenna for very far (maybe 20-25 feet, tops), then they'll have to run more or less parallel with the antenna until they go into the shack and hook up to the Johnson Matchbox type antenna tuner..

2. Center fed dipole, open wire feeders, SGC-type remote antenna coupler (probably the SG-230 unless you all have a better suggestion). Antenna coupler mounts at ground level inside a weatherproof enclosure, directly under the center of the antenna. Feeders run about 30 feet from the center of the antenna to the top of the enclosure. Coax and 12v power for the coupler runs underground to the shack.

3. OCF dipole, open wire feeders. The feed point will be quite close to being directly above entry point to the shack, so the feeders can almost run at right angles to the antenna until they enter the shack and connect to the Matchbox type antenna tuner.

Which of these options is likely to give me the best performance with minimum "RF in the shack" on 160 through 10?

RF in the shack is an important consideration because there are about 8 computers running aorund here including two commercial websites.

The radio in use will be an Icom IC-735 running barefoot. There are no plans to increase power output.

Thanks for any advice...

Eric WA1RKT

853. Antenna Mounting/Eathing Question

Source record: 155819

Hi, I'm looking for a bit of advice regarding earthing of antennas. I have a tilt over mast system with various antennas mounted on a stub mast which is mounted in a rotator (Yaesu).The highest antenna is an Icom discone ,below this I have a Datong active antenna for shortwave listening, below that I have an elevator with cross boom which supports a 70cm X yagii on one side and a 2M X Yagi
on the other. I believe that everything from the rotator up is insulated from earth at the moment due to the fact that it is mounted on the rotator and supported in the rotator cage by an insulating bush. The cross boom is also insulated from the elevator motor. Should everything (stub mast, cross boom etc.) be earth bonded to a good earth point (an earth rod)? I'm also looking for advice on the mounting of the Yagi's but I'll leave that for another day.
Cheers

> Transformerless drive of low impedance loads really became feasible with
> transistors.

Cathode followers may have very low source impedances, but the current needed to put any power into a low impedance load just isn't there. There will be some sort of thing (large inductor?) in a cathode follower between cathode and ground to provide DC continuity, and that will have a finite impedance at the frequency of interest. The load will also connect between cathode and ground (likely through a blocking capacitor). There is current flowing between plate and cathode (at the frequency of interest). The sum of the currents into the cathode pin on the tube socket is zero, so you can't send lots of amperes into an 8 ohm speaker that way even if you use lots of 6AS7s. The reason it works with transistors is that the collector current is high.

Transformers have a lot to be said for them.

David, who many years ago built a huge voltage-regulated power supply with a heck of a lot of 6AS7s in it; killing the VHF parasitic oscillations was lots of fun.

I agree. I spent my career designing test equipment that ultimately had to make measurements within its specifications. This puts a hard boundary on what you can permit yourself to believe without good evidence. What I found, over and over and over, was that:

1. As you say, equations can be incomplete. As was pointed out the other day, cables have a number of characteristics not covered by most formulas, such as air between the conductors and dielectric, and roughness of the conductors. Some time back I did a number of loss measurements on common cables and was never able to resolve the results satisfactorily with reasonably complete calculations. I'm certain in that case that the difference was greater than the measurement uncertainty, so I remain convinced there were significant phenomena occurring which were't included in the calculations. The only way to find out that your equations are complete enough, or just how good they are, is to compare their results with good measurements. Period. It's a classic case of garbage in, gospel out. You're calculating very precisely the characteristics of an imperfect model, and your results are precisely imperfect. Over the years I've been surprised over and over again, and examples of misplaced faith abound.

2. Until you verify your calculations with measurements, you can't have confidence that the equations are really calculating what you think they are. It's often useful to calculate the characteristics of an idealized model. But it's essential that you realize that's what you're doing, and not make the mistake of extrapolating that to mean that the model is necessarily a good representation of a real physical object.

3. Good measurements are very hard to make, and the most important part of making them is determining how good or bad they are. You have to be acutely aware of the limitations of your measurements just like you have to be acutely aware of the limitations of your mathematical model.

My objection to Reg's statement was the claim of "accuracy". I'm sure that his program competently calculates the characteristics of a hypothetical cable having precisely the dimensions and characteristics assumed by and put into the program. In that sense it's "accurate". But how good are the assumptions? How well does it predict the characteristics of a real cable you can hold in your hand? Apparently this hasn't been determined. I strongly suspect that carefully made measurements will produce more accurate values of characteristic impedance and velocity factor of a common cable than the program does. And I haven't heard any evidence to the contrary. Again, I'm not saying that it's not useful to do calculations on an idealized model -- shoot, I make my living selling software that does just that. But you always have to keep in mind what it is you're actually calculating.

It's not time yet, folks, to replace your test equipment with a ruler and computer.

I agree. I spent my career designing test equipment that ultimately had to make measurements within its specifications. This puts a hard boundary on what you can permit yourself to believe without good evidence. What I found, over and over and over, was that:

1. As you say, equations can be incomplete. As was pointed out the other day, cables have a number of characteristics not covered by most formulas, such as air between the conductors and dielectric, and roughness of the conductors. Some time back I did a number of loss measurements on common cables and was never able to resolve the results satisfactorily with reasonably complete calculations. I'm certain in that case that the difference was greater than the measurement uncertainty, so I remain convinced there were significant phenomena occurring which were't included in the calculations. The only way to find out that your equations are complete enough, or just how good they are, is to compare their results with good measurements. Period. It's a classic case of garbage in, gospel out. You're calculating very precisely the characteristics of an imperfect model, and your results are precisely imperfect. Over the years I've been surprised over and over again, and examples of misplaced faith abound.

2. Until you verify your calculations with measurements, you can't have confidence that the equations are really calculating what you think they are. It's often useful to calculate the characteristics of an idealized model. But it's essential that you realize that's what you're doing, and not make the mistake of extrapolating that to mean that the model is necessarily a good representation of a real physical object.

3. Good measurements are very hard to make, and the most important part of making them is determining how good or bad they are. You have to be acutely aware of the limitations of your measurements just like you have to be acutely aware of the limitations of your mathematical model.

My objection to Reg's statement was the claim of "accuracy". I'm sure that his program competently calculates the characteristics of a hypothetical cable having precisely the dimensions and characteristics assumed by and put into the program. With 2 acres, you could probably put up all kinds of wire
antennas, and there are plenty to choose from. A dipole is
probably the cheapest and easiest to get right for your first
antenna project. A random wire, like Richard described
is also easy, but the cost goes up, as you'll need a tuner.

As to the small beam - there are a number of them. I use
the MQ2, and am completley delighted with it. See
http://www3.sympatico.ca/tgmc/index.html
The upside to this antenna is the small space it needs, which
matches the small space I have. You can also spin it with
a TV antenna rotator and mount it to the gable end of your
house with standard TV antenna mounting hardware. The downside
to a small (ie "shrunken") antenna - any "shrunken" antenna - is some
lowering of performance over the same configuration in full size.
The downside to beams, in general, is cost. To get this antenna
installed on your house, it'll lighten your wallet by around $500:
370 + shipping for the antenna, about $60 for the TV rotator,
and you still have to buy the coax, mounting hardware, mast etc.
With a full size beam, you may have to go to a rooftop tower,
"real" antenna rotor etc. and of course you need more turning radius.
So your choice may be wallet dependant and/or space dependant,
or both. In the case of the MQ2, adjustment was easy - there was
none needed. If adjustment had been needed, there was not a need
for expertise (unlike the 6 meter yagi I built, which attempted to drive
me to drink), so a "first-timer" should have no trouble. That may also
be true for other small 20 - 10 beams, I don't know.

Installing wire antennas in trees is easy - just shoot a line over each
support tree and haul the antenna up. Installing wire antennas in trees
properly can be hard. "Properly" implies pulleys securely fastened
at at least one of the support trees and pulling the antenna up via a
rope through the pulley. It also implies that the antenna and support
ropes don't rub against anything. The idea is to keep the antenna
from breaking. So we're talking tree climbing, rather than just
shooting a line over a tree with a slingshot or bow and arrow.

MQ series (1 thru 4) of antennas at:
http://www3.sympatico.ca/tgmc/index.html

I would go 20 feet away, rather than stacking 2 antennas on
an extended TV antenna mast, for fear of bending the mast.
Someone with more experience than I can say whether my
fear of that additional 4' of mast and the antenna up there in the
wind is misplaced. The additional 20' of coax is irrelevant
at HF frequencies.

xganon wrote:

Hello

I will be using a wire antenna fed with twin feeder and will want to use a balanced ATU. Can anyone give me suggestions for a good balanced ATU. I won't be using more than 100W, will need balanced and unbalanced inputs with S0239 socket for output. I have looked at the MFJ range and a few others but would like to hear from people that use a wire antenna with twin feeder to a balanced ATU.

Thanks

Richard

Source record: 155917

.....and perhaps that's why we get into ham radio - to solve problems and deal with glitches. Anyway, I have an Icom 725 feeding into a 70 foot long wire through an AH 4 coupler. It tunes fine on all of the bands between 10 and 80, but occasionally on ten meters the SWR spikes and shuts down the transceiver. However, this problem seems to be intermitent. It will spike, I can retune and immediately be able to transmit again without a problem. I also can reduce the power to about 50 watts and this reduces the chance it will spike and shut down. I know the old doctor routine - if it hurts when you do that, stop doing it, but I want to run 100 watts.

Anyone got any ideas and thanks in advance.

Hi, I'm looking for a bit of advice regarding earthing of antennas. I have a tilt over mast system with various antennas mounted on a stub mast which is mounted in a rotator (Yaesu).The highest antenna is an Icom discone ,below this I have a Datong active antenna for shortwave listening, below that I have an elevator with cross boom which supports a 70cm X yagii on one side and a 2M X Yagi
on the other. I believe that everything from the rotator up is insulated from earth at the moment due to the fact that it is mounted on the rotator and supported in the rotator cage by an insulating bush. The cross boom is also insulated from the elevator motor. Should everything (stub mast, cross boom etc.) be earth bonded to a good earth point (an earth rod)? I'm also looking for advice on the mounting of the Yagi's but I'll leave that for another day.
Cheers

870. Power Supply for Linear

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-21 04:56:51 UTC
From: ehsjr@bellatlantic.net
Message-ID: <3BD254FA.CB5C2F62@bellatlantic.net>
Source record: 155824

I'm building a power supply for a linear amp. Never
done that before - and I'm running into more questions
than answers. The filament supply is already taken care
of, and I will build a separate screen supply. I'll undoubtedly
have questions about that, too, but for now I want to focus
on the HV supply. The amp uses 2 4CX250CR's.
I have a few BIG (12" long) 25 ohm resistors - I can use
one for the stepped input. The transformer is 115 input with
2 outputs: 1180 center tapped and 1460 no tap. There is no
current rating on the xformer, but it weighs enough to make me
believe I can get 1/2 amp with no problem. I've got 24 1N5408's
which I'll put in strings of 6 to make a bridge. I'll use the
1180 output to get about 1650 DC. I have 3 3500 volt caps -
1 8uf, and 2 4uf.
I have 3 chokes: non-swinging 10 henry 300 ma., swinging
at 25/5 henries, 30/300 ma, both 3000V, and 10 henry at
.250 ma and unknown (but high) voltage.

Questions:
Can I use the 300ma swinging choke in a pi capacitive input
filter? I figure current draw can go as high as 500ma, but
running ssb it has a low duty cycle. But, this is my first time,
and anyone accusing me of knowing what I'm doing is
going out on a limb! Would I be better off without the choke -
and would I need more than 16uf without it? Maybe I should
ask this way: with the parts I have, what is the best way
to go? I don't mind going to an inductive input filter using the
1460 volt secondary and getting ~1300 volts DC. I'm
not looking to get every last watt out of the amp.

Next: the bleeder resistor. I figure on using 2 series strings of
5 10 watt, 20K resistors at 100K per string , yielding
50K at 100 watts by parallelling the strings. Why does everything
I read aim at a 100 watt bleeder? Would I be better off with
a single string at 120K? It would have to dissipate a little less than
25 watts, while the string of 6 resistors would be able to handle 60
watts.

Ok, next, what am I overlooking? Will I need a cooling fan for
the supply? The enclosure will house the "protection electronics",
low voltage transformer, screen supply, relays, step-start resistor,
etc. I'm thinking of using another of those BIG 25 ohm resistors
- this one has a slider - to adjust the resistance on the primary side,
to adjust the secondary voltage. It seems to me that I'd be asking
for trouble doing that - but I don't know. I figure, in rough numbers,

2 ohms in series with the input would give me a 150 volt reduction under full load on the DC out. But I don't know what the effect of allowing the plate voltage to vary by 150 volts, no load to full load, would be.

Thanks for any pointers you can give me!

You may want to contact one of the Hams that stalks this newsgroup. His XYL
is a Novice and allegedly stars in a movie produced and directed by a guy
who calls himself Wrong Way.
I have yet to see the movie but I am told that she grunts out CQ in three
different octaves at speeds ranging from five wpm at the start of the movie
and builds her speed to 33 wpm at the climax.
I don't know the name of the movie but some of the guys here may be able to
shed some more light on it. I think the movie may have been made in Georgia
a few years ago and I saw a post that said the movie was being shown in the
Atlanta area.
Good luck with your search.

Reg wrote:
"---should the discrepancy be attributed to the formula or the
measurement?"

Often it`s blamed on the computer, and almost as often that`s wrong.
Usually the wrong programs or data were used. Anything can be misused.

People seldom blame mistakes on mathematical rules or on formulas such
as Ohm`s law. They`ve learned that these seldom err, so they must find
something else to blame.

If we want to find the frequency of WWV and find it at 9.99 MHz on our
radio dial, would we think something was wrong with the formula:
velocity equals frequency times wavelength?
I think not.

Best regards, Richard Harrison, KB5WZI

Hi OM,

I notice later in your posting, you are willing to go either C input
or L input filtering - it make a vast difference in the rating of
these particular components.

For C input filtering the diode chain is being stressed at roughly
twice Epk from your transformer. This is a classic blind side problem
if you are not working from a known, working design (that is to say,
those who roll their own often blow their rectifiers with this
distinction not observed).

It's late, I've been out dancing all night, otherwise I would look up
the ratings of these 1n5408's (you are probably covered anyway).
Remember to design to at least 150% of the maximum stress you
anticipate.

You'll probably have better luck in avoiding stray RFI floating around if you use the center fed dipole. You can work it on all bands, just as you can with the off center feds.

Can you tension the antenna enough to minimze sag? You may find, with the length you're going to be running, that center sag is a problem. May require a center support. Use fairly heavy gauge wire and put a good strain insulator in the center and see how it does, first.

Good morning, Bill.

I'll be running the IC-735 barefoot, about 100 watts. There are no
plans to increase that.

Eric

You don't mention what power level you will be supplying to the antenna system but the center fed with buried coax from the tuner to the shack will minimize the rf coupling from the feed lines to the shack.

With only 30 feet or so to the horizontal dipole elements, you will probably have some problem with higher power levels unless you have built the shack with RF shielding in the operating location.

On any of the above configurations it is important that you provide good DC and RF grounding to the operating location.

Not sure what an AH4 is but...
if it some type of automatic tuner rather than a manual one, you might have RF getting into the control circuits and causing it to mis-tune during use.

If that is the case, then better suppression of stray RF might solve the problem. Going to a manually operated tuner might help verify this as the source of the problem also.

Two that come immediately to mind are "Contact" which appeared a few years back and "The French Atlantic Affair", from the 1970s.

Although it's not amateur radio, "A Night To Remember" (1956?) depicts the role early radio played in the Titanic disaster. The 1997 James Cameron movie "Titanic" almost ignores radio.

Source record: 155836

I found this on a bulletin board like this one and decided to try it.

A little while back, I was browsing through a newsgroups,just like you are now, and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of ï¿½5.00! So I thought, Yeah right, this must be a scam but like most of us, I was curious, so I kept reading.

Anyway, it said that you need to send ï¿½1.00 to each of the 5 names and address stated in the article

You then place your own name and address in the bottom of the list at #5, and post the article in at least 200 newsgroups. (There are millions) No catch, that was it.

So after thinking it over, and talking to a few people first, I thought about trying it. I figured: ;what have I got to lose except 5 stamps and ï¿½5.00, right?

Then I invested the measly ï¿½5.00. Well GUESS WHAT!!...within 7 days, I started getting money in the mail! I was shocked! I figured it would end soon, but the money just kept coming in.

In my first week, I made about ï¿½25.00. By the end of the second week I had made a total of over ï¿½1,000.00! In the third week I had overï¿½10,000.00 and it's still growing.

This is now my fourth week and I have made just over ï¿½42,000.00 and it's still coming in rapidly. It's certainly worth ï¿½5.00, and 5 stamps, I have spent more than that on the lottery!!

Let me tell you how this works and most importantly, why it works.... Also, make sure you print a copy of this article NOW, so you can get the information off of it as you need it.

I promise you that if you follow the directions exactly,that you will start making more money than you thought possible by doing something so easy!

Suggestion:
Read this entire message carefully! (print it out or download it.)

Follow the simple directions and watch the money come in! It's easy. It's legal. And, your investment is only ï¿½5.00 (Plus postage)

IMPORTANT:
This is not a rip-off; it is not indecent; it is not illegal; and it is virtually no risk - it really works!!!! If all of the following instructions are adhered to, you will receive extraordinary dividends.

PLEASE NOTE:
Please follow these directions EXACTLY, and ï¿½50,000 or more can be yours in 20 to 60 days.

This program remains successful because of the honesty and integrity of the participants. Please continue it's success by carefully adhering to the instructions.

Technically, you will now become part of the Mail Order business. In this business your product is not solid and tangible, it's a service.You are in the business of developing Mailing Lists.

Many large corporations are happy to pay big bucks for quality lists. However, the money made from the mailing lists is secondary to the income which is made from people like you and me asking to be included in that list.

Here are the 4 easy steps to success:

STEP 1:
Get 6 separate pieces of paper and write the following on each piece of paper ;PLEASE PUT ME ON YOUR MAILING LIST;

Now get 5 US $1.00 bills or 5 Uk ï¿½ coins (or if you're from Scotland, notes) and place ONE inside EACH of the 5 pieces of paper so the bill or coin will not be seen through the envelope (to prevent thievery).

Next, place one paper in each of the 5 envelopes and seal them. You should now have 5 sealed envelopes, each with a piece of paper stating the phrase ;PLEASE PUT ME ON YOUR MAILING LIST;, your name and address, and a ï¿½1.00 coin or $1 bill. What you are doing is creating aservice. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate service and you are paying for it! If you have any doubts, refer to Title 18 Sec. 1302& 1341 of the Postal lottery
laws. Keep a copy of these steps for yourself and, whenever you need money, you can use it again, and again.

Like most of us I was a little skeptical and a littleworried about the legal aspects of it all. So I checked it out with the PostOffice and they confirmed that it is indeed legal! Mail the 5 envelopes to the following addresses:

1) Ms Alison Claren Grange Farm Barn, Hampshire RG25 2QBEngland
2) Ms J. Ferrere 2 Hemsley House, Streatfield Road, Heathfield TN21 8LA England
3) Ms T. Hutton 14 Blunden Drive, Langley, Berkshire, SL3 8WG
4) Ms V L Pirie 94 Provost Rust Drive Aberdeen Grampian Scotland AB167YL
5) Ms S E St John 60 Erw Non, Llannon, Llanelli, Carms Wales SA14 6BL
Now take the #1 name off the list that you see above, move the other names up (5 becomes 4, 4 becomes 3, etc...) and add YOUR Name as number 5 on the list.
STEP 3: Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups. (I think there are close to 2.4million groups) All you need is 200, but remember, the more you post, the more money you make!

PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by their carefully adhering to the directions. Look at it this way. If you are of integrity, the program will continue and the money that so many others have received will come your way.
NOTE:
You may want to retain every name and address sent to you,either on a computer or hard copy and keep the notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 in dark paper to reduce the risk of mail theft or if it is acoin, wrap it in tissue paper so that it does not slide around in the envelope.)

So, as each post is downloaded and the directions carefully followed, six members will be reimbursed for their participation as a ListDeveloper with one dollar or pound each.

Your name will move up the list geometrically so that when your name reaches the #1 position you will be receiving thousands of pounds inCASH!!!

What an opportunity for only ï¿½5.00 (ï¿½1.00 for each of thefirst five people listed above)

Send it now, add your own name to the list and you're in business!

---DIRECTIONS ----- FOR HOW TO POST TO NEWSGROUPS----------
Step 1)
You do not need to re-type this entire letter to do your ownposting.
Simply put your cursor at the beginning of this letter and drag your cursor to the bottom of this document, and select 'copy' from the edit menu. This will copy the entire letter into the computer's memory.

Step 2)
Open a blank 'notepad' file and place your cursor at the top of the blank page. From the 'edit' menu select 'paste'. This will paste a copy of the letter into notepad so that you can add your name to the list.

Step 3)Save your new notepad file as a .txt file. If you want to do your postings indifferent settings, you'll always have this file to go back to.

Step 4)
Use Netscape or Internet explorer and try searching for various newsgroups (on-line forums, message boards, chat sites, discussions.)

Step 5)
Visit these message boards and post this article as a newmessage by highlighting the text of this letter and selecting paste from the edit menu. Fill in the Subject, this will be the header that everyone sees as they scroll through the list of postings in a particular group, click the postmessage button. You're done with your first one!

Congratulations...THAT'S IT!

All you have to do is jump to different newsgroups and postaway, after you get the hang of it, it will take about 30 seconds for each newsgroup!

REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200

That's it! You will begin receiving money from around the world within days! You may eventually want to rent a P.O.Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will deliver it.

JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.

Now the WHY part:
Out of 200 postings, say I receive only 5 replies (a verylow example). So then I made ï¿½5.00 with my name at #5 on the letter.

Now, each of the 5 persons who just sent me ï¿½1.00 make the MINIMUM 200 postings, each with my name at #5 and only 5 persons respond to each of the original 5, that is another ï¿½25.00 for me, now those 25 each make 200 MINIMUM posts with my name at #4 and only 5 replies each, I will bring in an additional ï¿½125.00!

Now, those 125 persons turn around and post the MINIMUM 200 with my name at #3 and only receive 5 replies each, I will make an additional ï¿½625.00!

OK, now here is the fun part, each of those 625 persons post a MINIMUM 200 letters with my name at #2 and they each only receive 5 replies,that just made me ï¿½3,125.00!!!

Those 3,125 persons will all deliver this message to 200 newsgroups with my name at #1 and if still ONLY 5 persons per 200 newsgroups react I will receive ï¿½15,625!

With an original investment of only ï¿½5.00! AMAZING! When your name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $5.00 to names on the list, putting your nameat number 5 again. And start posting again.

The thing to remember is: do you realize that thousands of people all over the world are joining the internet and reading these articles everyday?, JUST LIKE YOU are now!!

So, can you afford ï¿½5.00 and see if it really works?? Ithink so...

People have said, what if the plan is played out and no one sends you the money? So what! What are the chances of that happening when there are tons of new honest users and new honest people who are joining the internet and newsgroups everyday and are willing to give it a try?

Estimates are at 20,000 to 50,000 new users, every day, with thousands of those joining the actual internet. <Remember, play FAIRLY andHONESTLY and this will really work I found this on a bulletin board like this one and decided to try it.
A little while back, I was browsing through a newsgroups,just like you are now, and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of ï¿½5.00! > How do you wind that pipe without kinking? Easy to avoid or
> special tool needed? TIA,
==========

Was a few years back. I was interested in Q calculations and measurements.

I wound an 18-turn coil using 8mm = 0.315" (a little less than 3/8") copper pipe on a 100mm (4") diameter green plastic gas-main pipe. I used it for a time in a low-loss unbalanced-to-balanced tuner.

No problem with kinking. A minor problem was a small tendency to spring away from the coil former before the ends are anchored. I am left with the impression it could happily be wound round a much smaller diameter, say 2", without trouble. Copper is a lovely metal to work with.

Can't remember wall thickness or grade. There are various grades of copper used for different purposes. The soft stuff I used was similar to that used to convey oil around machinery or in hydraulics. It can be bent round fairly sharp corners without severe distortion. I think the softer material is the purest copper and is therefore also best for high Q coils.

Hint: because it is slightly springy, anchor one end of the coil to the former before winding. Drill the hole for anchoring the other end *after* winding. It is difficult to predict beforehand where it might be.

Tie a length of string to the end of the winding. Wrap the string round the former a few turns to hold the winding in position while anchoring. Or just leave it there. The second coil to be wound will be a neater job. ;o)

It may not be obvious but I needed no special tools. Just wound it
by hand like 18 AWG.

What would be likelyhood of success of using a wire bed frame from a queen size bed as the ground radial for 5 band hf. I have two ground rods at the base of antenna?

Also could it be used for vertical 2 meter?

Many years ago there was a "short subject" movie series called "Pete Smith Specials". A ham built a homebrew rig using a bunch of cake pans etc as chasses.

The ham contacted a station speaking Chinese language. Real DX. When the camera was redirected, it turned out the Chinese-speaking station was a Chinese ham in a house right next door.

The vertical will really be in your way while you sleep and the wife
will hate it. That hole in the ceiling/roof will certainly leak also.

It was a nice movie, although Jodie Foster had a weird way of calling "CQ." I'm
not sure she'd actually heard any hams on the air...

>and "The French Atlantic Affair", from the 1970s.

The French Atlantic Affair was a mini TV series -- I don't recall seeing it, but
I read the novel, and it's one of the best fictional books about ham radio
you'll ever read, if you can find it (out of print -- but Amazon.com has it,
used).

It was written by Ernest Lehman, K6DXK, who is one of Hollywood's top
screenwriters (King and I, West Side Story, North by Northwest, Sound of Music,
Who's Afraid of Virginia Wolf, etcetera). There's a lotta detailed stuff about a
ham running an Atlas 210 rig.

I would suggest you use a search engine such as Google, click on "groups"
and enter "balanced tuner". You will get thousands of hits since this is one
of the most popular topics of all time and everyone has something to say.

Probably a bit too British for most Merrycans, but there is always Tony Hancock in 'The Radio Ham'. Not really a movie... one of a BBC TV half-hour comedy series from the 60s. Considered 'a classic' over here, along with 'The Blood Doner'. Of course, in reality there are no radio amateurs as ludicrous and incompetent as the character portrayed by Hancock.... well, maybe a just few...
73,
Ian.

Frequency used a Heath SB301 receiver for transmitting which was quite
amazing. The VOX was also very sensitive since one could speak at low volume
from across the room.

And the really intriguing part is that all that talking took place with a Heathkit SB-300 or 301 receiver! With the cover removed so that you could see the fire-bottles.

So, I guess that if you can talk back in time and thereby alter the future, as the story unfolds, then a receiver works as well as anything. But my 301 in 1970 would never do anything except listen! <:}

Hygain used to publish an engineering application note kind of thing
on phasing of verticals. You might contact HyGain/MFJ and see if that
is still available.

If that is not availble from them, and if you can handle multi-page tiff files I can scan my copy and email it to you. It's about 4 pages in length. Let me know by email if you strike out at HyGain.

Another good book for reference is the ON4UN "Low Band DXing" book.

I put up a pair of Hygain HyTowers phased on 75 about 10 years ago and found both of these to be useful in the design process.

901. 2MT beam/rotator ok to mount on chiminey?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-21 16:26:46 UTC
From: zaax@aol.com
Message-ID: <20011021122646.16935.00000956@mb-fi.aol.com>
Source record: 155852

I recently purchased a Yaesu FT-100D and would like to use it for high-speed meteor scatter on 2 metres with WSJT. Now the tricky part is to get a 2 meter beam up. I would prefer to mount it on my chiminey. Is this practical or should I look at mounting it to my roof with a tripod?
I have seen straps that wrap around the chiminey to hold a mast. Is there any problem using these?
The largest vertical portion of the chiminey that I can use is around 18 inches. Is this enough to hold the mast, rotator and beam?
BTW I would get a beam like the M2 2M12 or a Cushcraft 13B2 and a rotator such as the Hy-Gain CD-45II.
Any thoughts on this will be most welcomed.

Thanks
Zack

Been there, done that...I should've guessed the quite native sounding
German pinning out the meter on the old DX-392 was just a couple
blocks away.

Had me thinking I'd built one heck of an antenna, until he ID'd with a
W5 call.

Are you looking for a way to show support for the country's war against terrorism, or support for those directly affected by the September 11 attack? Do you have space on a tower, mast, or other antenna support? If so, think about this.

Towers and other support devices can make great places to hang an American flag. And, they can be lighted with a simple floodlight so they can be visible at night.

I have done just that myself. I have a flag at about 45 feet, illuminated at night. You can see what mine looks like on my website at:
http://www.qsl.net/w0osk

I hope others will consider doing this as a way to show support for the effort.

|1180 output to get about 1650 DC. I have 3 3500 volt caps -
|1 8uf, and 2 4uf.
|I have 3 chokes: non-swinging 10 henry 300 ma., swinging
|at 25/5 henries, 30/300 ma, both 3000V, and 10 henry at
|.250 ma and unknown (but high) voltage.
|
|Questions:
|Can I use the 300ma swinging choke in a pi capacitive input
|filter? I figure current draw can go as high as 500ma, but
|running ssb it has a low duty cycle. But, this is my first time,
|and anyone accusing me of knowing what I'm doing is
|going out on a limb! Would I be better off without the choke -
|and would I need more than 16uf without it? Maybe I should
|ask this way: with the parts I have, what is the best way
|to go? I don't mind going to an inductive input filter using the
|1460 volt secondary and getting ~1300 volts DC. I'm
|not looking to get every last watt out of the amp.

"Modern" design philosophy is to do away with chokes and use a high value filter
capacitor. That said, I have a supply using a (resonant) choke input filter in
my 8877 amp. Like you seem to be doing, I limited myself to parts on hand and I
felt that a capacitive filter would give too much plate voltage. Consequently,
I have a power supply that weighs about 150 pounds. Ouch.

You will change your mind and will want every available watt out of this amp.
<g>

I'm not familiar with the "CR" version of this tube but I assume that 300-350 V on the screen would be in the ballpark. I believe that with only 1300 V on the anode, I would have a problem with excessive screen current unless I loaded the plate very heavily. Therefore, I would shoot for closer to 2000 V.

If I deleted the choke, then I would use more capacitance than 16 uF. I would then use the primary surge limiting resistor. One a foot long is probably overkill but if I had room, what the heck.

I would bite the bullet and buy some high capacitance 450V electrolytic capacitors and use a series string of them. I would then use the 'bleeder' resistors as equalizing resistors across the capacitors. Six capacitors with a 20K resistor per would give a me 2700 V rating with a 'built-in' 120K 60W bleeder. For safety reasons I would use second series string in parallel with the output. This would also improve the regulation slightly.

|
|Next: the bleeder resistor. I figure on using 2 series strings of
|5 10 watt, 20K resistors at 100K per string , yielding
|50K at 100 watts by parallelling the strings. Why does everything
|I read aim at a 100 watt bleeder? Would I be better off with
|a single string at 120K? It would have to dissipate a little less than
|25 watts, while the string of 6 resistors would be able to handle 60
|watts.

See above
|
|Ok, next, what am I overlooking? Will I need a cooling fan for
|the supply? The enclosure will house the "protection electronics",
|low voltage transformer, screen supply, relays, step-start resistor,
|etc. I'm thinking of using another of those BIG 25 ohm resistors
|- this one has a slider - to adjust the resistance on the primary side,
|to adjust the secondary voltage. It seems to me that I'd be asking
|for trouble doing that - but I don't know. I figure, in rough numbers,
|2 ohms in series with the input would give me a 150 volt reduction
|under full load on the DC out. But I don't know what the effect of
|allowing the plate voltage to vary by 150 volts, no load to full load,
|would be.

One possible hiccup is the transformer. You say that it has two secondary outputs, so I assume they are separate windings. While the weight of the transformer is some clue to the power handling capability of the core, it doesn't say a thing about the current rating of the individual windings. If you pick a winding that was previously used to light a neon sign, you have a problem. I would run some load tests to get a handle on this.

What has been overlooked? Well... you have a lot of questions that suggest a lack of experience around high voltage. This isn't bad, we all knew nothing about a lot of this stuff when we started out, and what you are doing is a good way to learn. But BE CAREFUL!.

Most new hams have never experienced h-v equipment and are used to sticking their hands into gear that has only 12 VDC inside.

I am not suggesting that you follow anything that I said above, except BE CAREFUL. Everywhere else, I was telling you what I would do, not what you should do.

|
|Thanks for any pointers you can give me!
|

Keep one hand in your pocket.

Believe it or not, in the sixties, when I was young and would try anything to make a contact on CW, I worked a KH6 on 10 meters off a bedspring leaned up against the wall in my friend's room. It loaded well, and I guess, was a pretty fine radiator. Dont know that I could do it again, but what a thrill.

Hi Richard,

From the perspective of a former metrologist and current software programmer (a designer of massive formulas) - I will add there is not a jot of difference between formula and measure.

Measurement is formulaic and its goal is to reduce a question to numbers to be churned through - guess what? - a formula. To limit the discussion to a tedius distinction that formula must slavishly conform to one representation, y = x + 1, and deny its implication in the simple act of using an ohm-meter would be parochial.

It is impossible to remove formula from measure; equally impossible to remove measure from formula.

I would say it will be an "unreasonable fee" judging by the Motorola dealers I have competed with over the years. Typically $75 per radio, even in large numbers. My shop made good money programming Motorola radios because they charged so much.

hey zaax
i think what you have in mind will work fine i would go with an old TV rotor though cause they are smaller and less weight and after all the antenna you want to turn with it is only about 15 feet long so you dont really need a big rotor to turn it also keep in mind if you are going to do what you plan you will need very good low loss coaz either 9913f or lmr400 or if you have a long run 7/8 hard line and get yourself a preamp something mast mounted you will be trying to hear signals bouncing off small rocks in space you will need all the help you can get
good luck

Be careful. A chimney is not the best mount in terms of the
damage that could possibly result. There may even be laws
against it in your area -- there are such laws in many
places, and the law is not about antennas, but mounting
anything on a chimney. Good Luck!

Re: 'Frequency' radio errors...

Not as bad as the Bruce Willis 'Die Hard' movie where everyone (Police, Bad Guys, CBers, Fire Department, Air Traffic Control, etc.) all used a single channel. And all their walkie talkies were full duplex and you could tell instantly if someone 'hung up' on you. Very distracting.

Hi Richard,

I'm into speakers (can you tell?). I heard that years ago they actually made a high impedance speaker that would directly couple to a tube output stage. No transformers needed - the voice coil of the speaker was actually the high impedance. I guess it didn't work very well though as I'd never heard of anything like that recently.

Check out my site if you want to learn a whole lot about speakers.

Richard Clark wrote:
"It is impossible to remove formula from measure; equally impossible to remove measure from formula."

Yes, Richard Clark is the expert on this subject. Nevertheless, I think you can draw nearer to an actual true value through repeated measurement, common sense as to acceptable data, and averaging. You are less apt to be successful with multiple formulas because the right formula is not so easily sent astray. All various formulas tend to be variations of the same formula anyway. A formula is simply less sensitive to perturbations than a measurement.

Best regards, Richard Harrison, KB5WZI

I have noticed, after reading all of the replies, that no one has actually answered my question yet.

Somehow it got turned into a tube transmitter design forum. That's interesting too, but regardless of the transmitter (lets assume that it's a 50 ohm output) how do I turn a big, grounded, metal warehouse into a 50 ohm antenna.

Aside from this project, I would also like to use the building as a receive antenna for AM radio. That's probably what I'm gonna use it for most. I know it's just not as easy as attaching a wire to a beam - after all, it is grounded and I don't want to short anything out. I was thinking it may be like a gamma match - kind of as the type some hams use to turn their entire tower (also grounded) into a 160m vertical. I think I saw that in the handbook somewhere once. My other thought was some kind of homemade coils - wrapped around a PVC pipe former - or something like that.

I don't know. That's why I asked.

Paul

I may build the tube transmitter for another frequency band and use the
160 Khz crystal and an op amp or something. Solderless breadboarding
should be fine at that frequency.

Thanks, Wes. Some real good info for me in your post.
My replies are interspersed. You seem to grasp
precisely "where I'm at" and your pointers are
very much appreciated. And you are dead center
on target telling me to BE CAREFUL!

Wes Stewart wrote:

> I assume this is at VHF, cuz I can't imagine using these tubes at hf these days.
> If I am wrong, why?

Wes, this is a military surplus amp with continuous coverage of 2.0
to 30 Mhz. I've already modified it to cover 1.8 to 30 - adding
6 meters without ruining HF would be a challenge.

> "Modern" design philosophy is to do away with chokes and use a high value filter

Great! That explains why I haven't seen chokes in the schematics
I've found. I wondered about that. And you are right - these are
parts on hand. It'll weigh about 100 lbs (estimate) if I use the stuff
I've got.

> You will change your mind and will want every available watt out of this amp.
> <g>

Groan! Well I hope not, but ... I havn't seen you wrong yet.

Point taken, not disagreed with, but not understood. Can you direct me
to the text(s) I need to study so that I'll understand the relation between
screen current and plate voltage? What I understand about it so far
is clearly incomplete. I know that I want to keep the screen current
very low (actually I want to keep it at 0) - the maximum for this
tube is 12 ma. I intend to build protection circuit to shut the amp
down if the screen current exceeds 6 ma in either direction. I have
a copy of the EIMAC book, which I'll study again. Often, I have
to read this stuff over and over and over before I really "get it".

> If I deleted the choke, then I would use more capacitance than 16 uF. I would
> then use the primary surge limiting resistor. One a foot long is probably
> overkill but if I had room, what the heck.

I'm putting the supply inside an old microwave oven cabinet, so there
is enough room. The resistors came out of an elevator bank control
rack that was given to me. I was wrong - they are 10 1/2 inches long
and 1 1/4 inches diameter - I just measured one.

> I would bite the bullet and buy some high capacitance 450V electrolytic

> the output. This would also improve the regulation slightly.

I may have to do that. I had not considered that the equalizing resistors
across the capacitors in that configuration would also serve as bleeders -
but of course they would. Thanks for pointing that out - I would likely
have overlooked it if I decided to string the caps rather than using oil
filled units.

Another excellent point I had not considered.

> What has been overlooked? Well... you have a lot of questions that suggest a
> lack of experience around high voltage.

EXACTLY. While I've repaired HV sections in TV's, I have never
designed anything at HV. I've been spending a lot of time reading
about insulation properties of various materials, worrying about
lead dress, contemplating running the wires through teflon tubing
etc. I love this stuff that I am forced to explore when I decide
to brew something new. I never had any interest in linear amps
(I still don't, as an operational aid. I like barefoot) until I realized
I could learn something by undertaking this project.

r.r.a.boatanchors a few weeks ago.

The movie "Hatari" with John Wayne has lots of radio action. They work
both a base station boatanchor and go mobile on VHF (??) several times.
No one uses a call sign and it must have been quite an experience for any
ham back then to be DX'ing and suddenly stumble upon hard-drinking, cursing
Trappers ragchewing illegally (?) on the radio. It's shown several times a year
on cable, check it out.

. A truck and a 4X4 going full tilt across the African Savanna in
pursuit of a charging Rhino that repeatedly rams the truck with his big ugly
tusk while the two teams stay in touch and "work" the rhino via VHF (? based
on apparent antenna length). Fun movie, but not for women's libbers. Hard to
say if it's a cool take on radio given the multi-mode "action-style" usage or
poor continuity due to lack of legal Ham procedure. You decide. One of those
movies made back when men were men and women were proud of 'em.

And here's another,.....

"The Thing" , James Arness vers. Actuall, I think it's more
properly called "The Thing From Another World !".

No ham per se, but I recall milcomms, arctic base stations
(portable?) , and maybe aero-mobile as well. I recall a few
scenes of Radio Op. twiddling dials over static, etc. while
captain urges him to "keep trying!!". Or somesuch . Maybe
not much for Ham ,though a real fun flick Those of you who
feel good grounding is irrelevant suggest you watch the
shocking climax. Others know what I mean.<grin>

Yep, my parents had an old Philco radio using that design. That's
the component that failed and there was no replacement.

You may want to contact one of the Hams that stalks this newsgroup. His XYL is a Novice and allegedly stars in a movie produced and directed by a guy who calls himself Wrong Way.
I have yet to see the movie but I am told that she grunts out CQ in three different octaves at speeds ranging from five wpm at the start of the movie and builds her speed to 33 wpm at the climax.
I don't know the name of the movie but some of the guys here may be able to shed some more light on it. I think the movie may have been made in Georgia a few years ago and I saw a post that said the movie was being shown in the Atlanta area.
Good luck with your search.

Not quite hamming but I think in one of the "Gilligan's Island" episodes
use is made of a Hallicrafters receiver. Maybe also, in, god forbid,
"Fantasy Island". Thankfully, I never saw the latter and don't remember
the former. "Plan Nine from Outer Space" has some cardboard boxes that
look like radios.

I'm dying laffing, not from the responses, but from the LACK of
responses as if this is a hallowed subject that nobody wants to admit to
publickly.
Loading up bedsprings, window screens and downspouts is part of an
ongoing educational process.
Try it...it may be better than your last experiment. In deference to
the original poster, using the springs for only a ground plane is pretty
tame. You should strive for better! Co-phased kings, etc. My first
75m contact was with a window screen. Judicious experimentation proved
it worked better out in the yard with 100 feet of wire running to it. I
since worked 160 countries on 80/75 after I figgered out that the screen
wasn't the trick.

943. Computimg SWR from R and X values

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-22 01:41:42 UTC
From: Will White <googlyelmo@earthlink.net>
Message-ID: <3BD37952.261CD77D@earthlink.net>
Source record: 155793

I was fiddling with some interesting little RF modeling programs (Reg Edwards' "dipole1" and "t-tuner", among others), to find feeder input values of R and X, then using these to calculate the L and C values required of a T-tuner to yield a good match, when I realized that I don't know how to calculate SWR using R & X vs 50 ohms. I can't find a formula to do this in any of my several ARRL HBs, or my 1991 version of the Antenna Book, my other books, or the web sites I know of that trade in such info. I know how to figure SWR given two pure resistances; it is simple division. What to do, though, with the reactance ohms?

It would be handy to know how to shake the numbers this way. Say, for example, R equals 185 Ohms & X equals -317 Ohms at the input of my feeder, my frequency is 7050, what would my SWR be, relative to my transceiver/tuner 50 Ohm output?

Additionally, one often sees the expression "R +jX" referring to 'Z', a complex impedence. Is this the simplest statement of Z's value, or can it be reduced further to a single number value, say n ohms?

Source record: 155796

Every measurement of any kind is subject to uncertainty and entails comparing something with a local standard. The local standard, which invariably has an uncertainty, is (or ought to be) eventually traceable to THE International Standard. Or should we say THE UNIVERSAL Standard.

THE Standard is defined in mathematical terms written on paper and has ZERO uncertainty. We have progressed beyond the stage when the King's foot was the standard of length.

So the formula takes precedence over the measurement. The buck stops here ! The Law says so.

Reg.

Speaker Repair wrote:
"I heard that years ago they actually made a high impedance speaker that would directly couple to a tube output stage."

Yes. Millions of them actually in the 1920`s. Most radios used magnetic armature type loudspeakers. Problem was too much moving mass in the armature and its attachments for fidelity. The electrodynamic speaker with its low mass moving voice coil was an enormous improvement in fidelity.

Electrostatic speakers have been made in large enough sizes to have low frequency response (Quad for example) and these are capacitors which don`t have enough farads to be a low impedance but they have problems enough of their own.

Best regards, Richard Harrison, KB5WZI

Each to his own I suppose. I saw it in the theatres when it was 1st released
and was thrilled by it as a little boy. Also, think the theme song about the
cute baby elephants is a classic and maybe won an Oscar. None of this
makes it a good movie, but like I said, each to his own. Besides, even
today I still lust for that pouty French girl and wonder why. Ce'st la Vie.
The only REALLY good JW movie was "True Grit", IMHO.

> [The "Two Richards" were discussing 'formula' and 'measurement'.]

I (simplistically) view 'measurement' as the domain of the experimentalist and 'formula' as the domain of the theorist. Obviously in this simplified and extreme view of measurement versus formula, I'm referring only to the purest of derived formula - not those formula that are based on somebody scratching a 'best fit' line through the noise and proclaiming that k=76.35 (or whatever).

Q: If he had lived so long, what time would it be at Albert Einstein's house ? A: 12:00, 12:00, 12:00, ... [a theorist is incapable of setting the clock on their VCR].

Excuse me for drifting slightly off-topic....it drifts back onto the conversational thread a few paragraphs down.

My most recent experience (from a project management point of view) of the battle between 'measurement' and 'formula' has been with application of Geometrical and Unified Theories of Diffraction (GTD/UTD) as applies to predicting the far field performance (antenna gain coverage pattern), and the near field coupling (EMC issues), of antennas on structures. Structures in this case refers to moderately large airplanes. For some strange reason, certain people (members of the 'Anti-Swiss Cheese Airplane' movement) seem to prefer that we make some predictions *before* we make some holes.

For completeness I will mention that the application of GTD/UTD begins at frequencies just about where other numerical methods start to become computationally intractable. Where NEC (et al) can handle the lower frequency range (and therefore a reasonable number of segments), the forte of GTD/UTD is the 150MHz to 15GHz part of the spectrum where NEC-type methods might require borrowing the NSA's computer bank (*).

Development of GTD/UTD seems to be a typical Physics battle. On one side are the theorists with their intellectually-derived formula that describe the behaviour of spherical, superconducting chickens (an old joke). On the other side are the poor experimentalists that spend their days trying to take accurate measurements on their carefully-prepared spherical, superconducting chickens.

In the case of GTD/UTD, the theorists have done the diffraction mathematics for a family of 'canonical' shapes which include flat plates and wedges, cones and truncated cones, cylinders of circular or elliptical cross section, and so forth. These shapes are used to model the structure in question. Given a reasonable selection of canonical shapes, it is possible to model a complex structure (such as an airplane) to a reasonable degree of fidelity. It is my understanding that the diffraction coefficients for

these canonical shapes have been rigorously developed from first principles.

The experimentalists role is to verify the diffraction coefficients by way of direct measurement. When the measurement differs from the formula results, then the battle begins !

(I trust that at this point you can see the family resemblance to the Subject line of this posting.)

In the GTD/UTD case that was related to me, the experimenter came up with some measurements that seemed to cast some doubt on the diffractions coefficient formula that had been derived by the theorist. Apparently, after some analysis (by the theorist) of the measured data, the discrepancy was revealed as being ("obviously") caused by low level reflections in the measurement chamber. The experimenter was told to install some better absorbing material into his chamber (better than -40dB) and come back when he had some "decent" measurements.

Spherical, superconducting chickens... ...you can see what I mean when I claim that formula are never wrong, only incomplete.

Although the foot and meter have been defined as so many 'something
fundamental or other', last I heard the kilogram was still a chunk of metal.

See: http://www-ec.njit.edu/~grow/measure/sld011.htm

If they have replaced that definition, then I missed the memo.

Speaker Repair (Paul) wrote:
"---no one has actually answered my question yet."

A warehouse doesn`t hold much promise as an antenna for AM radio. It is connected to ground all along its lower edge and has no insulated pieces to work against this structure.

An insulated counterpoise suspended above the building might make the structure into an acceptable antenna system.

For FM, the structure can make a slot antenna. 100 MHz has a wavelength of 3 meters. A slot of 1/2-wavelength (1.5 meters) with a width of say 1/4-wave (0.75 meters) wil have the characteristics of a dipole. The sides of the narrow slot width can be tapped at their middle for a drivepoint.

The drivepoint impedance of the slot is related to the impedance of a similar dipole that the slot outlines by:
Zslot = 35,476/Zdipole
For a 72-ohm dipole that is 493 ohms.
If you want 50 ohms, it needs transformation. There are toroidal transformers on r-f core material, L-C networks, transmission-line transformers, tapered lines, etc to step down the impedance by a factor of 10 (voltage ratio of the square root of 10).

If you need to distribute AM signals inside the building which shields them from receivers in the building, that is a slightly different problem. The shielding of the building means a distribution amplifier can wirelessly couple the receivers inside if the antenna outside is sited far enough away so that the gains and losses add to less than one so the system won`t oscillate. The antenna leadin may require shielding.

Best regards, Richard Harrison, KB5WZI

950. Surplus high power CU 1699 / FRT RF Balun.

Cross-posted to: rec.radio.amateur.antenna,alt.ham-radio.hf

To who it may concern,
I have been trying to find information everywhere about a set of high power baluns that are military surplus. I have two of these. They look like power pole transformers and have a 50 Ohm coax (LC) connector on the bottom, and have a set of 600 Ohm outputs (balanced) on the upper side of the can. They are filled with about 10 gallons of PCB oil. They stand about 3 ft. tall and about 14 inches in diam. There is an ID tag on each one with the following info :

Coupler - Transmission line CU - 1699 / FRT,
2 to 32 Mcs, 50 Ohm unbalanced coax - 600 Ohm balanced.
25KW AVG. - 50 KW PEP.
Mfg. for Navy Dept., Elec. Systems Command by Granger Associates.
Contract # N00600 - 67 -C -0231.

I know they would be perfect for an antenna (50 Ohm feed) far away from the equipment with a long open wire line run / or coax from the xmitter to the xformer, then run open wire out to something like a rhombic.
I would like to know more about them. I haven't found any info from Granger or Fair Radio. Are there any replacement cooling oils to take the place of the PCB stuff? Does anyone still sell any of these surplus units or have they all been snatched up by the Rhombic owners?. What were they originally used for ?
Someone once told me there used to be ads in one of the ham radio magazines years ago for sale, but they may have been different ones.

Thanks, Steve W8LAC

All I need now is at least 10 or 20 acres & a lot of # 8 copperweld.
!.

Ahhh... if you put rectifiers in series to meet the PIV rating, aren't ya supposed to put some high value resistors and pF capacitors in parallel with each diode to ensure that the reverse voltage doesn't get "concentrated" on the fastest diode ?

Hi OM,

Richard, in another posting discusses electrostatic speakers (found in
the posher retail establishments as far as I can tell); so I will
confine myself to a scientific curiosity: the flame speaker.

I recall this gem from the 60's in either Scientific American or
Popular Electronics. They began by taking the standard amplifier
output and putting it through a step up transformer. At the cold end
of this transformer they attached a DC power supply of 600V. The
earth end of the supply was then bonded to the metal head of a propane
torch.

Light the torch,

Turn on the DC supply,

Place the hot end of the transformer secondary into the flame,

Turn on the music.

Reports were that the quality of sound was very good, where for greater bass response, you needed a longer flame. Also noted was that the efficiency of the sound generation increased if the flame was doped. The only drawback (aside from BTU's) was the flame jet hiss.

It sounds like he's trying to use it like a coffee can feed, or maybe some sort of slot antenna variant.
Unfortunately, the wavelength is likely too long. The closest ham band is 160M, He's looking at 600 meters on the low end of the band. The quarter-wave stub element alone would be a monster!

You aren't, and you don't need to. Your idea of the gamma match has
merit. That in itself will satisfy the 50 Ohm requirement of the rest
of the system.

Hi Paul,

This gamma match is going to be luck of the draw (I'd take a chance
however).

With a thin radiator, the geometry clearly defines the constraints of
current boundaries. That is, you can reasonably be assured of
consistent results with time tested methods. Using a building creates
a more nebulous situation where standing waves are 3 dimensional.

The point of contact for your gamma match - will it hit a hot spot or
a dead zone? Kindalike the cat's whisker and the crystal. I would
suggest you plan on doing this several times to find what works. If
your building presents many options (attachment points and grounds),
or even a couple, it could be a good gamble. It might be even simpler
if you loop coupled to the skin of the building. This would allow

freer experimentation and no connectivity issues.

No. In the "good 'ole days" when diodes were not so uniform and were
processed differently, that was true. Today's diodes tend to
avalanche (zener) at a reverse voltage that is lower than the
destructive point. In a series string, the reverse current in an
avalanching diode is limited to the reverse leakage current in the
diodes that are operating out of breakdown.

It's multipath problems. If you have enough time, just keep resending the data until your error checksums are zero. That's the simplist, cheapest way to deal with multipath. If the vehicle is moving significantly during a burst (over a few cm) you will be driving into black holes, and your checksums will never work. Try shortening up the bursts, so that the vehicle is essentially fixed in place during the duration of the burst. Some packets will go through, and some won't. That's life. Jim

What kind of feed? Loop or Gamma? What speed does
the capacitor turn at? You might possibly be passing
the tuning point so quickly that your meter doesn't
register. Possibly short on the capacitor? There isn't much
more I can think of that could possibly cause problems.
Good Luck!

965. how do I make alternative "wire" antenna's

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-22 06:14:14 UTC
From: Martine <vest34@wish.net>
Message-ID: <1003731369.392804@news.l3.wish.net>
Source record: 155816

My name is Peter Stam from the Netherlands and I work in the Dutch Royal Army in a recon platoon of the 11 Airmobile Brigade.
Recently I was send on a course for HF- radio manpack using skywave.
The 2 standard antenna's we use are wire-antenna's with a dipole or windom construction. During several excercises I noticed that those antenna's didn't always work properly.
My question to you all is : can you send my idea's for alternative-antenna's and/or background information about antenna-technics.
I heard about "mirrors" on the ground using metal-wire's, antenna's you could aim, socalled inverted-V antenna's and much more but I haven't a clue how it works.
If you do send me info., please remember that these antenna's should be easy to build in a sometimes mountaines area using tree's

Thanks in advance, Peter Stam

966. Help, antenna questions...

Hello Guys,

I have received so much help from you people in the past, that I thought maybe you could help me again. I wish to build an antenna, the design is located at: http://hem.passagen.se/sm0vpo/antennas/6dbvhf0.htm
and I have a few questions. I have built this antenna previously, but the PVC pipe that I used as a framework proved to be too flimsy for permanent installation, other than that the antenna worked wonderfully. This time around I wish to do things a bit differently...
Questions:
1. Can I spray paint the antenna (so that it is not easily noticed in my tree)?
2. Can I use 10 GA steel wire (this is what I used last time, and still have some left over), or is another metal better (all I seem to find is either copper or steel wire in the 10 GA size)
3. After connecting the coax to the balun, can I run it back along the boom towards the upper and lower elements and then down the lower element? I wouldn't have the coax touching the elements exactly, but I wanted to build a sturdy wooden "T" shaped frame and run the coax on the other side of the wood from the elements and the balun. I would then mount the antenna by the wood that extends a foot or two below the lower element, thus making the boom much shorter and less obvious.

Let me know, please. And thank you for your help.

Hi Peter,
get a good HF antenna book in your library. The ARRL Antenna Book
seems to be the best world's compendium about antenna subjects, but I
suppose you can get other good ones. Or visit the pages of W4RNL at
http://www.cebik.com/radio.html ,there is really much about antennas.

Try the paint - both the mark and color. If it is not too lossy and
does not degrade the antenna, you can.

> 2. Can I use 10 GA steel wire (this is what I used last time, and still
> have some left over), or is another metal better (all I seem to find is
> either copper or steel wire in the 10 GA size)
Steel is probably the worst material for antenna making due to its
losses, ferromagnetism and corrosion. Copper seems to be the best one.
Brass is good in warm territories, but it often breaks when frozen.
Aluminum and duraluminum are good, only it's hard to solder them.

> 3. After connecting the coax to the balun, can I ...
Post your question to http://members3.boardhost.com/sm0vpo/ . The

969. B707 'Spike' antenna questions

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-22 10:03:03 UTC
From: John Mackesy <mack@melbpc.org.au>
Message-ID: <9r0qr8$7re$1@possum.melbpc.org.au>
Source record: 155720

Not exactly amateur, but someone might know...

I need some info on the dimensions and performance of the 'spike' antenna used on B707, e.g. how long, what diameter, how effective for long range communications and directivity (if any). Also characteristic impedance in the 2-30 Mhz range, is any form of (capacitive?) loading used, if anyone has that info.

John Mackesy (Collins 618T operator)

A 1M diam loop will resonate 10-30 MHz with maybe 100 pF at the low end and stray at the high end .. you're probably in the AMBC band with that diam and vacvarcap.

Richard Clark wrote:
"Place the hot end of the transformer secondary into the flame. Turn on the music."

Several names were given this process. I recall "ionophone" and "plasma speaker".

My experience with the plasma speaker is accidental. It comes from contact with a transmission line carrying 50 KW of shortwave power. A 100 KW transmission line was just a few feet away, so it could have been worse. I could have bumped into the output of more than a dozen transmitters.

At that plant it was not unusual to hear a sudden burst of program sound. It announced the vaporization of a hapless bird trying to land on an energized transmission line in a burst of brilliant flame. Sometimes they actually landed and all that was left of them were their claws clamped on the cable.

I carlessly found a deafening plasma voice in my ear one afternoon when I straightened up atop the plant roof under a 50 KW line. I was too big to evaporate like a bird, but my ear was very red and in a few hours it looked like a lump of coal. I`d been a bad boy, so that`s what I got for Christmas.

Might try using circular polarization (CP) antennas at each end. Single bounce reflections will be reflected with the opposite sense and largely rejected by the antenna. CCCP helps to take a bite out of multipath.

978. Ant Question, Random Wire and Mag Loop

Source record: 155736

Hello,
I currenly live in an apartment and have 33 feet of random wire out
running around the outside wall to a tuner. I was thinking of looking
into one of the MFJ Mag Loops (15-40 one, even the 10-30 one)
I was wondering how much of a difference will I notice if any?

I have found the random wire seems to work pretty well, all things
considered. No DX just US stations but it works.

Thanks
-Ryan

An excellent source already recommended is the ARRL Antenna Book. In Chapter 6 of the 19th edition is a section: "The Loop Skywire".

Most of the h-f operators I know have settled on a horizontal loop such as this (more or less). They are mostly limited in land area and tree supports but they enclose as much area as they can and get most of it up as high as they can. That`s it. It always seems to work pretty well.

Best regards, Richard Harrison, KB5WZI

981. My G5RV experience...

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-22 13:59:55 UTC
From: Sideband <sideband@spam.me.not>
Message-ID: <3BD4270E.C1B6D77E@spam.me.not>
Source record: 155731

I finally got the G5RV up, and let me say that it's a vast improvement over the inverted V I was running for 20 meters and running thru the tuner for 40 meters..

The odd thing is that I don't even need a tuner for 20 or 40. The SWR on this antenna is below 2.5:1 across 20 and across 40 both. Here's another oddity.. it tunes on 160.. Of course I couldn't find anyone to talk to down there to see how well it worked on 160, but it tunes up nicely.

So, here's the question... Does anyone know of a net or a group that meets on 160 meters? When? What frequency?
I'd really like to see if I got a weird one, if my installation is causing false SWR readings, or if this thing actually works and tunes on 160 meters....

TIA, and 73 de KC8RKQ

> division. What to do, though, with the reactance ohms?

Rho is the magnitude of the reflection coefficient.

Rho squared = ((R-Z0)^2 + X^2)/((R+Z0)^2 + X^2) = P-/P+

Take the square root to get Rho. Then SWR = (1+Rho)/(1-Rho)

ok thanks for the info so far.....

I will look into a dip meter ... thanks

I am using the 1/5 loop....

I can vari the speed on the motor to the cap 0-100% remote

I have today built a 1mtr circle loop with the 1/5 loop inside and a
different cap , and that seems to work fine, so maybe the 3mtr square loop
is to big???

what freq will a 3mtr square loop resonate at ??????????????????

I am looking at working 40 an 80mtr bands only
my beam will cover 10-20

so I think its down to the cap or to big a loop size

> The odd thing is that I don't even need a tuner for 20 or 40. The SWR on
> this antenna is below 2.5:1 across 20 and across 40 both.

Not odd at all. The G5RV was designed for 20m. It is a resonant 1.5WL
on 20m and the series section transformer is 1/2WL on 20m. It is also
not odd that it is a good match on 40m. The combination of a 3/4WL
center-fed antenna with 1/4WL of series section transformer is in
the appropriate low impedance range.

> Here's another
> oddity.. it tunes on 160.. Of course I couldn't find anyone to talk to
> down there to see how well it worked on 160, but it tunes up nicely.

The standard G5RV is very inefficient on 160m but the efficiency is
not zero.

I just got my ticket and am now in the "where can I string up the antenna?"
stage. I see two choices:
1) There's about 40 feet in the clear or
2) 80+ feet, but I need to go through some tree branches.

Obviously, my choices are greater with the 80 ft. run. If I use a coated
wire for the antenna, can I get away with it or will the contact with
branches and leaves make it a likely disaster?

Any comments would be most appreciated.

Thx e 73

990. ATR30 tuning question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-22 15:41:50 UTC
From: Rudy Marcelletti <rudym@net-link.net>
Message-ID: <3bd43e5f$0$37105$272ea4a1@news.execpc.com>
Source record: 155741

ATR30 is a pain in the butt to tune on 160 meters. My antenna is 240 foot long dipole (1.950MHz) and fed with 150 feet of 450 ladder line (14ga. stranded). Mounted inverted V with apex at 95 feet. The ladder line goes to one of those MFJ/W9INN "remote balun" boxes and I have about 35 to 40 feet of RG-8 type coax into the shack. I have an MFJ986 tuner that will take this antenna all the way down to 1.1:1 no problem anywhere on the band. I am lucky to get this antenna down below 1.5:1 anywhere on 160. On 1.880 the Trans cap is about 7, the Ant cap is and the Inductor is about 10 (is max inductance). Same settings on 1.950 but inductor is about 18. And all this is after fiddling with settings using an MFJ259 analyzer through about 3 sleep mode cycles--about 10 minutes! I really have to work at tweaking this thing for every bit a match below 3.5:1 The ATR30 matches this antenna up pretty good on the other bands. I knew going to a "3 knob" tuner would be slower than a "2 knob" but this is crazy. Any suggestions from you ATR30 owners or other antenna gurus?

Your feedline is approaching 1/4 wavelength at 1.8 MHz and transforms the antenna feed point impedance to a very high value. Tuners generally work better when the impedance they are tryin to match is somewhat closer to 50 ohms. You would have to change your feedline (length or type) to present a more suitable impedance to the tuner on 160. (This would also change impedances at the tuner for the other bands.) Another option would be to change the length of the antenna to accomplish the same task.

Hi Paul,
Congratulations and welcome. As far as your antenna, I have an 80m dipole that is in a large pine and 30% of the legs run through the branches before exiting. I cut it for 3750. and the swr dip is right near there. So String away in the tree.

thanks for all the help...I have found a bad connection on the
cap........its works now.....mind you I may have to play around with it a
bit more as I have to much cap on 40mtr.......but its ok on 80 and 160..
so a bit of adjustment and all will be ok..

thanks again for your help

998. Re: Multi-element Quad ant. in EZNEC ???

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-22 17:50:32 UTC
From: "Joe Giacobello, K2XX" <k2xx@swva.net>
Message-ID: <3BD45C68.2DD484E6@swva.net>
Source record: 155753

I have successfully modeled and built a multi-element, multiband quad within the 500 segment limitation imposed by EZNEC. I define success by the fact that there was very little or no adjustment required to obtain SWR minima within each of the bands, and that the actual shapes of the SWR vs frequency curves were quite faithfully predicted. (I did not attempt to accurately measure F/B and compare it to the model, but I may do so in the future. Also, the antenna works well.) My results were confirmed by both L.B. Cebik (W4RNL) and EZNEC's author, Roy LewAllen, using professional level modeling software, which provided more than enough segment capability.

The antennas is a six band quad with four elements on ten through 20 meters and seven elements on six meters. The constraints that were imposed on the design were a 24 foot boom, equidistant spacing between all elements for each band, separate feeds for each band and maximization of forward gain consistent with a reasonable match to 50 ohms over a reasonable bandwidth. The actual antenna utilized a boom mounted remote switch to select the driven element for the active band.

In my situation, I compensated for the 500 segment limitation, by assuring that the active band and its two closest neighbors always met EZNEC's conservative guidelines. I reduced the number of segments below the guidelines on the two bands most distant from the active band until the 500 segment limit was met. I have the comparisons provided by LB tabulated together with my data on Lotus 1-2-3, if anyone's interested. The only differences between my results and his is that he predicted slightly higher forward gain (0.2-.4 dB). F/B differences were less than 0.5 dB.

I had previously gone through this same modeling exercise with an identical antenna at a different QTH, but in that case comparisons between the model and actual performance were quite poor. However, LB pointed out to me that while the software requires all the inactive driven elements to be closed, in the actual antenna they are open to one degree or another, depending on the length of the coax links between the remote switch terminals and the driven element feed points. Thus, the actual antenna did not faithfully represent the model.

In the latest antenna, 1/4 wavelength (electrical) coax links were used between each band's switch terminals and the respective antenna feedpoints. The switch terminals for all the inactive bands were left open so that the corresponding antenna feedpoints were electrically closed (shorted) at the other end of the 1/4 wavelength coax link to faithfully emulate the model . The comparison between the model and the actual antenna were, as I have said, quite gratifying.

Ian`s loop is about 40 feet in circumference. Fig 19 on page 5-14 of the 19th edition of the ARRL Antenna Book shows a loop this size tunable from about 2.5 MHz with 300 pF to about 10 MHz with 5 pF.

The Antenna Book says:
"The resonant frequency of the loop can be readily found by setting the receiver to a desired frequency and rotating the capacitor (by remote control) until signals peak. The peak will be very sharp because of the high Q of the loop.

Best regards, Richard Harrison, KB5WZI

Either a dipole or vertical/ground plane antenna...for low end
of six, element length is ~54-56 inches....cut long and trim down..
Actual length can be determined by 234/f(Mhz)= length in FEET...
That is a 1/4wave on 6....if you cut it to that length, and feed
with 50ohm coax, a vertical would have a slight SWR on it...

A simple idea if you have a LARGE metal ground area (like a metal plate
or similar 5ft by 5ft or so) is use a Larsen NMO-150 magmount antenna..
DONT cut the whip (use the 49 or 51 inch long whip). Works across the
entire 6mtr band like a champ...and yes it also works on 2 as well :)
Im using one right now...

Will, KD7BFX wrote:
"Is this the simplest statement of Z`s value, or can it be reduced
further to a single number value, say in ohms?"

Not exactly without the loss of some information because magnitude alone
does not completely describe the function.

But, the Cartesian form of R+jX can be converted into a magnitude on a
particular angle (the polar form). This impedance magnitude is thanks to
Pythagoras, and is the square root of the sum of R square and X square.
The angle is arc tan X/R.

1004. Re: Antenna Specialists M-2117 40-50 MHz ant. help?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-22 18:30:42 UTC
From: "Christopher W. Boone" <Cboone@earthlink.net>
Message-ID: <3BD464FB.A65AF3A9@earthlink.net>
Source record: 155755

If you have access to a 50-54 Mhz radio and a Bird wattmeter (dont
use a cheap SWR meter here), you can determine where the antenna
is resonate now and then trim it down...
Better if you can borrow a MFJ antenna analyzer...that will tell you
exactly where the antenna is resonate..

If the radio will go below 50Mhz, GREAT..if not, you can still get
an idea..

Key the radio at the lowest freq in the range you may suspect the
antenna is on (say 45 Mhz or so) at 1 watt or less...(do this into
a dummy load 1st to check output!)....With the Bird inline, check
reflected power and go up or down in 500 kHz steps until you start
to see the reflected really starting to drop...(using a 1watt slug
in the bird of course)...You will then have to move in smaller
increments until you get right to the correct freq that has NO reflected
and 1watt forward...that is the resonate freq...see how long that is..
if it doesnt fit into the 234/freq MHz = length in ft, then its
not a quarter wave....if it doesnt fit into 468/freq Mhz = length
in ft, its not a 1/2wave (maybe a 5/8 wave and if it is, that will
be 585/freq in Mhz= length in feet (or multiply the length bt 12 for
inches!) Then set the radio to 50.5 or so....if there is a telescopic
element, try moving that 1st!! Dont CUT until you have to!!
Try moving the element shorter in height and see if the reflected at
50.5 starts to drop...adjust other elements if you can...
You may need to check reflected say at 50.00 and then 50.5 to see if it
is coming down...Make sure you continue to see the reflected dropping..
if you cannot shorten the antenna any more without cutting, cut some
of the tubing at a spot (say no more than 3-4 inches off) where you
can easy use a hose clamp to attach it back if needed..

Continue to trim until you get the element length down to where the
reflected is lowest in the 6mtr band (if you want to use it on
SSB, trim it for lowest around 50.2 or 50.3...this will cover the
SSB and AM section of the band 50.1-50.5...if you want FM use, trim
it for lowest reflected at 52 Mhz or maybe 52.5...this will cover
most if not all of the FM segment of the band.

Good luck!

Source record: 155756

I have just descovered QRP and am thinking about designing a multi band vertical antenna. I have several military vehicle sectional whip antennas made of copper plated steel. The sections vary in length between 3 and 4 feet, I am thinking about varying the length for each band by adding sections to get somewhere just short of a 1/4 wave for all bands from 20 to 10M and using a tapped coil to resonate the antenna. On 40M and maybe even 80M the coil will have to be quite large as the antenna will have a maximum length of 15 feet, does anyone know of a formula or some software that will help me work out just how big the coil will have to be.

Thanks in advance.

In the undisclosed town where I ran a Kenwood dealership, the local MSS was it's own worst enemy. Their attitude was better than a large advertising budget on our part. Even new Moto radios bought from them had a $75 programming fee tagged on for EVERY one. They didn't even like to talk to hams about radios, unless you knew the owner who was a ham and were in his "clique".

We programmed all our radio sales for free, and made reasonable changes for free during the life of the radio. For a competitor's sold radios we would charge a few bucks at most, and for a large quantity we did it for the current bench rate. For Ham's that were not pests it was usually free, provided we had time. They might have to wait because customers took priority. However, there were a few hams that wanted reprogramming every couple of days, and didn't care if you were busy- they paid the same rates as the customers. They really should have bought ham radios that were self programmable...

Source record: 155759

A ham friend of mine asked me something and since I did
not have a good answer I thought I would post to group. He
wants to put in some 1/4 wave buried ground radios for an
inverted L long wire. He has been using this on 160M
and other bands. He asked if enameled wire could be used
for these. At first I said I did not think this would be
very good because of no electrical contact with real ground.
I got to thinking about my answer later and thought almost any
buried wire is going to get an insulating corrosion layer on it
eventually over time. Maybe electrical contact is not really
that important. Perhaps capacitive coupling between the ground
and the wire is sufficient to make the radials work. Anyone have
any thoughts about this?

A complete analysis of G5RV performance (except radiating pattern which is well known anyway) at *any* frequency is available from website below. Download program VARNEY.exe in a few seconds. Not zipped up. Run immediately. User-friendly.

Or any other antenna fed via tuner + coax + balun + twin feeder + centre-fed dipole.

For radials, any wire will do in a pinch. I have used insulated "zip cord" I had in a bulk spool with lots of success. You are correct that ANY wire will corrode eventually and have to be replaced. The key is lots of radials, the more and the longer the merrier. The radials themselves act as the counterpoise, so direct electrical contact with the earth is not necessary. Look at it this way...If your earth conducted that well in the first place, you could just pound in a ground rod and not need any radials. But almost no earth is that good. So you throw down as much wire as possible and operate :-)

Jack up the building. The higher the better.
Knock a 6-foot rod into the ground underneath the building.
Feed the transmitter, via a tuner, between rod and building.
It's very simple really.

Here's one for you. Its titled "High Frequency" its an Italian movie from late 80's or early 90's. Its about a young boy who uses his late fathers radio to contact a satellite monitoring station in Switzerland. Together they solve a murder mystery. Its not great but its worth watching. They use Yaesu equipment. 73"s Al

Hi all -

I am going to run a 2 element quad, what is the most "efficient" way to match 50 Ohm coax to it? Does a gamma match or some other network "better" than a 1/4 wavelength piece of 75 Ohm coax (regarding bandwidth, power handling, etc.)??? Welcome all comments.

Thanks,

Scott.

If you mean a 1/4 wave from the balun, then I am about 20 feet longer at 1.8, and if you include the coax length, then I am even longer yet. The book indicates that 150 to 190 feet of feed line is OK for 160 meters and for 80 meters 140 to 160 feet is OK. What I can't figure is that the MFJ will match it but the supposedly better Ameritron won't. I'll try adding 10 more feet of wire on each end and see what happens.

IIRC, it looks like a broadband whip due to its diameter. I saw the data in one of the antenna handbooks years ago. Its about 10 inches in diameter at the base and around 20 feet long. The one on the C141 is fatter and shorter. Collins had a heck of an autotuner to match it. Unfortunately, I don't remember the number. As long as you keep your antenna above 30,000 feet, you should get out well.

That's exactly the difference between "ground radials" and a "counterpoise"-
the insulation. The radials probably have a small edge in efficiency, at
least for a while.

I my experience a 2-el quad matches quite well on its own to 50-ohm
coax. I tried a gamma match once but my creation was so flimsy it
wasn't worth the effort.
May not be the most efficient but it got me 300+ countries.

Is it just me, or was anybody else annoyed at the way the prof could
make anything in the world, but couldn't make one of those
bicycle-generator things he was so fond of power some sort of
transmitter?

The receiver they always had, and some other standard boat stuff
should have provided all the components he would've needed for a
really simple QRP CW rig, and I doubt you'd have to sit on one
frequency sending SOS for too terribly long before someone heard and
started DFing your signal.

Maybe the island had really restrictive CC&R's... ;)

==========
Dave,

An insulated radial wire is insulated only at DC.

There is a capacitance between the wire and the soil.

This capacitance is in series with the base of the antenna and is tuned out by the ATU simultaneously with the antenna tune-up. The radio operator doing the tuning-up is not aware of the extra series capacitance.

Now it is the thin layer of soil immediately adjacent to the wire which contains most of the resistance between the wire and God's Good Earth.

But light the faggots, here comes a heresy -

By insulating the wire the RF loss resistance in the soil DECREASES because the soil immediately in contact with the un-insulated wire has been replaced by a low-loss dielectric which has a larger surface area in contact with the soil than the bare wire had.

In practice, ground loss remains much the same for ordinary insulation thicknesses.

If the insulation was VERY thick (like an elevated radial?) then the capacitance to ground would be small and more turns would be needed on the coil to tune it out. So loss in the tuning coil might increase.

To sum up - at HF it doesn't matter a tinker's cuss whether radial wires are insulated or not.

But an insulated wire will last longer in the ground which is worth
thinking about.

|
|Wes, this is a military surplus amp with continuous coverage of 2.0
|to 30 Mhz. I've already modified it to cover 1.8 to 30 - adding
|6 meters without ruining HF would be a challenge.

Okay, I understand. My concern is that these tubes are very easy to drive and
not particularly up-to-date in the intermodulation distortion department. If
you have a 100W exciter, it will be difficult to throttle it down so as to not
drive the amp too hard. If you are QRP then you should be okay.
|
|> "Modern" design philosophy is to do away with chokes and use a high value filter
|> capacitor. That said, I have a supply using a (resonant) choke input filter in
|> my 8877 amp. Like you seem to be doing, I limited myself to parts on hand and I
|> felt that a capacitive filter would give too much plate voltage. Consequently,
|> I have a power supply that weighs about 150 pounds. Ouch.
|
|Great! That explains why I haven't seen chokes in the schematics
|I've found. I wondered about that. And you are right - these are
|parts on hand. It'll weigh about 100 lbs (estimate) if I use the stuff
|I've got.

Unless you have a swinging choke (and even then to some extent) you must have
some minimum current through the choke to keep the supply in the choke-input
mode. In the old AM days, the constant carrier loaded the PS and kept it in
"regulation." Choke input supplies were the norm. With SSB, particularly class
B amps, with little idling plate current, the supply voltage would soar to the
same voltage as a capacitor input filter unless you drew a bunch of bleeder
current. So the change was made to capacitor-input filters and the capacitance
value was increased to lower the dynamic output impedance and supply the peak
current required by the linear amplifier.
|

|
|Point taken, not disagreed with, but not understood. Can you direct me
|to the text(s) I need to study so that I'll understand the relation between
|screen current and plate voltage? What I understand about it so far
|is clearly incomplete. I know that I want to keep the screen current
|very low (actually I want to keep it at 0) - the maximum for this
|tube is 12 ma. I intend to build protection circuit to shut the amp
|down if the screen current exceeds 6 ma in either direction. I have
|a copy of the EIMAC book, which I'll study again. Often, I have
|to read this stuff over and over and over before I really "get it".

The purists might groan over this description but we will ignore them for the time being.

Others are probably groaning because this discussion belongs in rec.radio.amateur.homebrew but I assume you will eventually be connecting this amp to an ANTENNA, so we'll stay here <g>

Because you have a plate "tank circuit", the instantaneous pk-pk plate voltage will, depending on drive level and loading, swing plus and minus some value that is centered on the dc plate voltage. (If you have the same issue of the Eimac book that I have, see figure 15 in section 3.2)

With little drive and/or heavy loading, the pk-pk swing is small. The reason loading is involved is thus: The tank is a transformer, stepping up the nominal load Z (50 Ohm) to some higher value at the anode of the tube. "Light loading," means that the step-up ratio is higher than it would be under "heavy loading."

Ohm's law is in full force here, so __for a given power output__ light loading means there will be a higher pk-pk swing at less anode current. There is a formula that is commonly used to estimate the require plate load resistance:

Rl = Eb / (k * Ib)

where Eb is the dc plate voltage, Ib is the plate current and k depends on the class of operation and varies from 1.something to 2.

Now, with an ideal zero-bias grounded-cathode triode, the instantaneous plate voltage can swing from 2 * Eb down to 0 (the cathode potential) without protest. The plate current swings from some peak value set by Rl down to zero.

If we now add a second (screen) grid to the tube and set its voltage to 300 V a number of things happen to the way the tube performs (see the Eimac book) but the one of interest is what happens when the plate voltage tries to swing toward the cathode potential (zero). When the instantaneous voltage gets down to 300 V, the screen is just as "attractive" as the plate is to the little electrons that are zipping along away from the cathode. (This isn't exactly true because of geometry, but remember this is a simplified explanation)

As the plate voltage swings even lower, the screen effectively becomes the plate, intercepting more and more electrons. You know what this means.

To keep the screen dissipation within specs, the negative going plate swing must be limited to no less than the screen voltage (300 in this example). This means it must be limited in the other direction too, so you have effectively given up 600 V of pk-pk swing. Unless you want to reduce drive and give up power out, you must increase loading and/or up the anode voltage to compensate.

|
[snip]
|
|> What has been overlooked? Well... you have a lot of questions that suggest a
|> lack of experience around high voltage.
|
|EXACTLY. While I've repaired HV sections in TV's, I have never
|designed anything at HV. I've been spending a lot of time reading
|about insulation properties of various materials, worrying about
|lead dress, contemplating running the wires through teflon tubing
|etc. I love this stuff that I am forced to explore when I decide
|to brew something new. I never had any interest in linear amps
|(I still don't, as an operational aid. I like barefoot) until I realized
|I could learn something by undertaking this project.

At the voltages encountered in most amateur level amps, lead dress and insulation are of some importance, but are not as critical as the voltages in CRTs. What you must remember is that the current capability of the amp supply is enough to be lethal. The anode voltage in the CRT will probably not kill you, it will just make you jerk your hand and impale it on the nearest sheet metal screw.

One other thing. You should take a look at Ian's web site at:

http://www.ifwtech.com/g3sek/boards/tetrode/tetrode-1.htm

for some ideas, if nothing else.

====================================

Jon,

Download from website below small programs VERTLOAD, LOADCOIL, TOPHAT & SOLNOID2 Made near Birmingham, England. Between them you can predict the radiating performance of *any* short or not so short, loaded vertical. What-if? Compare one with another. Find the optimum height at which to locate a loading coil. It may be lower than you think so locate it in the tuner for easy band-changing. Choose your own antenna and coil dimensions. Find number of coil turns needed and wire sizes. Get it almost right first time!

Download in a few seconds. Not zipped up. Run immediately. User friendly.

Happy thinking !

Regards, Reg, G4FGQ
Free Radio Design Software.

Yes, I forgot about the stainless steel. It is not feromagnetic (at
least certain types) and does not corrode. I forgot because here in OK
it is a bit difficult and expensive to buy stainless steel rods and
tubing. It is quite hard to cut and drill the stainless steel, too.
Nevertheless, a silver plated stainless steel might be the really
ideal antenna material. :-)

Dear Colleague

surfing on the web and searching for a cubical tribander I have found the CUBEX antenna (see at www.cubex.com) I asked for info on the italian HAM forum and people told me that they prefere a 3 elements yagi has the HY GAIN TH3MK4 instead of the 2 elements cubical quad by CUBEX (friends told me to have tested personally). Well my idea is that it's impossible that a 3 el.yagi 3 band works better than a 2 ele quad monobander for 10/15/20 also if you have to do a lot of attention and maintenance to the 2 quad.

Please if anybody has the cubex let me know on private your impression

The "transmission line equations" for no-loss or very low-loss lines involve only the circular trig functions and are easy to work with on most calculators. There is no end of programs around that work with these equations, including those for lossy lines that involve the hyperbolic functions. They are generically known as "Smith Chart" programs even though few of them actually plot or display a Smith Chart.

Check Reg Edward's web site for a good start on programs of this sort.

An EXCELlent tool for this sort of thing - yeah, pun intended! - is the free XLZIZL spreadsheet for Excel. A search should reveal the URL for download. I is most complete and yet is easy to use. And it does plot a real Smith Chart!

Source record: 155696

I am going to put up a vertical to be used on 80 and 160. On 80 it will be a full quarter wave
in length. A am planning on putting an 80 meter coaxial trap on the top connected to 2 loading
wires that will be used on 160. I have already laid out 60 133 ft radials.

I am wondering on how long I should make the mast. If I make the mast approximately 65 ft it
should resonate on 80 meters. If I then add the trap and loading wires will that detune the antenna
on 80 meters? I know the trap and loading wires are bound to interact so I how do I come up with the correct combination for mast height/trap/loading wires that will play on both bands without
having to raise and lower the mast over and over to come up with the correct values.

Thanks,
Harry - W0PIY

Kent, K9EZ wrote:
"If you are doing SSB/CW you should try and stay with horizontal polarization (i.e. dipole or loop)."

That`s good advice if that`s what everybody else is doing and you want to talk to them.

Is horizontal polarization any better for line-of-sight than Vertical? If you are cross-polarized with a station you are trying to work, you may suffer 20 dB loss. See "Polarization" page 20.49 of the 1998 ARRL Handbook. Above 50 MHz the Handbook says there`s no proof of superiority of either polarization, in general, except that vertical polarization is used for mobiles and repeaters.

Terman says the best polarization to use at VHF depends on terrain and convenience.

It is convenient to be able to communicate with others.

Best regards, Richard Harrison, K5WZI

Thanks ... AGAIN!
More great stuff in your post. Your explanation of
screen/plate voltage/loading relationship is very
understandable and helpful.

And yes - this is all going to lead into questions about the antenna(s)
in use here, eventually. Q's like: can I use a phase meter to determine
when the xmiter is "looking at" a resonant antenna; can I combine the
phase meter with an RF current meter; how do I determine how
much power the antenna (or instrumentation used in conjunction with it)
can handle ... but I want to wait on those Q's until I've done more
experimentation and a lot more reading.) I'm not ready for those
questions yet.

Jon, G2FHF wrote:
"I am thinking about varying the length for each band by adding sections to get somewhere just short of a 1/4 wave for all bands 20 to 10M and using a tapped coil to resonate the antenna."

Lengthen to just longer than 1/4 wave, then use a variable capacitor to resonate the antenna. You get lower loss, greater convenience, and better behavior.

>Harry - W0PIY

Harry, not seeking to answer your post but to expand the question, I wonder if a slightly different vertical arrangement might not be easier with which to work?

Folded monopole antennas for the broadcast band do work quite well. I know that from the experience we had at WTAW that Lawrence Behr did on a three element such directive array which used about a ten foot spreader at the top of a shorter element and brought down the other wires in a cage form down to the near-ground area. It was fed from the tip ends of the folded over wire cage.

I've been meaning to experiment on the possibility of doing a similar thing with an 80 meter stick, and then doing two things.

1.) For 80 I thought that I could simply use a relay and bring over the tip of the down wire back to the main mast. I would join it to the main mast. The main mast then would become a 'fatter' 80 meter vertical. In my case, I feed it as a gamma matched hard grounded stick. The coax feed goes right to the capacitor that connects to the gamma section which correctly taps into the tower up about the 30 foot mark. We'll not go into the exact science if this is a for-real just gamma match deal, or is, in reality, somewhat of a linear loaded game, OK? It's probably both. It works.

2.) For 180, I would open up the tip of that down lead at the base of the vertical. Instead of feeding the gamma match section of the main mast, simply move the coax feed line tap over to whatever matching transformation was needed for the 160 meter operation.

On 160 meters, this would then operate as a folded monopole antenna. The total length of it would thus be only about the customary 65 feet or so.

The question comes as to how much shortening of the main mast would be needed to compensate for the 'fatter' main element, I should think. That's back, in a way, to your original question. As I think it was Mae West that once said, "Dahling, there are some things you really can't model; you have to experiment!"

An expansion of that idea was thought about as to trying that same technique on a full sized 80 meter four square array. Of course, on 160 meters that would result in a 1/8th wave element spacing. And that, so noted, I think raises the question about feed impedances and negative dis and dat. However, it has been reported that 1/8th wave spaced veertical arrays do work, I think, here in the forum.

As well, it would seem that such a combination on 160 would still be better than being poked with the conventional sharp stick, wouldn't you think?

--> Sleep well; OS2's still awake! ;)

Karl Beckman wrote:
"How long? At least a quarter wavelength!"

An astute observation. The FCC makes applicants prove they don`t need so much if they apply for a medium wave broadcast license and propose something shorter.

We recall that resistance of the earth path from an antenna is proportional to the distance from the antenna and inversely proportional to the cross-sectional area of the earth involved. Area grows faster than the distance from the antenna. The idea is to reach out with a low-resistance path to where a large area is involved Then we need a low impedance connection.

Paradoxically it is found that more radials is usually better than longer radials. The old guys at RCA determined that 120 radials was just about perfect. You can do well with quite a few
less.

Best regards, Richard Harrison, KB5WZI

Ok Clint; you don't have to charge anyone for any professional service like boat/RV repair, Waiter, Electrical, Plumbing or even to build them a house in the country if you are
either independantly wealthy, have a filthy rich parent or are heavily subsidised party elite or movie star (or perhaps your time is over-valued?).

As a Brother Ham, I was wondering if you had a spare mansion in Beverly Hills and a pension for me to retire to? (I noticed Bill C. went to New York instead)

Pardon the belch;

<soapbox>

All that seems to be changing for economic and security reasons, etc. Now they just get rid of the technicians and substitute installers, and ship the radios away to a depot where they perform a wholesale flat-rate repair. This way, security is maintained while employing wetback, kid, prisoner or volunteer for manual or less skilled technical operations like mobile installations and "picking frequencies", or even a god person such as a federal agent or police officer who may have any of the above executed for touching one of "his" radios.

One side-effect of this, is that when a sophisticated system goes down, the search is on for a competent repairman, as many have disappeared since the system was first put on line. Someone may in fact have to be flown out while the clock is ticking. Of course the ultimate answer to all this would be a complete phase-out of privately owned systems completely, and complete takeover by carrier owned systems with leased portable units such as Nextel or a few of the cellular carriers.

This almost does away with the slave labor, because the portable unit doesn't require installation, and can be easily shipped to depot level for programming and repairs.

All this cuts the overhead and "problem" of having to hire someone just to program radios, change fuses and replace antennas (and occasionally to fix a repeater, dispatch console or link) who may need to be shot in the head as a security "concern" by virtue of excessive experience.

I have a 2 elemnt 5 band Cubex Quad on an 8 foot (2.4 Meter) Boom.
I feed it with the remote coax switch, separately on each band, using 1/4 wave matching coax on the bands where required. I do NOT use the single feed to a 5 band balun, which they sell.

The boom is 33 feet (10 meters) above ground.

It beats the performance of the 3 element 3 band (TA33 JR) Yagi it replaced.

Think of a 2 element quad as a 2 stacked 2 element yagis.

My matching is not perfect, but is under 2:1 across each band.

I am happy with the Cubex. The major differences in quad antennas of the same design would be the strength, as there are no traps for one company do differently from others. While I am using a direct feed, you can see from articles that some use a Gamma match and others use Hair pin or similar matching systems. Cubex sells an optional 5 band common feed "balun" arrangment but they reccomend that you use the separate feeds.

Only Maintenance has been to keep things tight once a year. I have not found a good way to waterproof the ends of the coax at the feed points.

With the short boom, I can reach each end of the quad by leaning back on my climbing belt.

I did have a structural problem and a boom failure, but that was related to a local wind turbulence in the near by trees. If you have winds that would tend to "roll" the quad, I reccomend the heavy duty boom. I have reinforced mine with a "splint".

Message-ID: <9r4dor$7ad$1@news.tribune.com>
Source record: 155708

I have a 2 element Cubex quad, with a 5 position coax switch, and one feed line to the shack.
The kit supplier provided the "cut lengths" for matching sections for each band, but said one was not needed for 20. (They will currently sell you pre cut and terminated matching sections).

I found that due to the local conditions, the 20 meter element was 112 ohms. It was a simple matter to change the feed from the box to the loop to a 75 ohm and get an acceptable match.

With 5 bands on the quad the match is not 50 ohms on all bands.

Using one of the various brands of antenna analyzer, you can find the impeadence of each loop, then cut a matching section of the appropriate length to match the 50 ohm to the shack.

I like the Autek analyzer because it is small enough to fit in my pocket, and wieghs less than the MFJ.

From: Steve Woodruff <nospam.sjwoodr@nospam.email.com>
Message-ID: <9r4euo$98q$1@flood.xnet.com>
Source record: 155709

I am considering the 4/5-BTV vertical antennas by Hustler. I may
choose the 4-BTV and use a dipole for 80/160 operation... but my
questions are generic enough to be valid on both models. If you
have/use one of these antennas, i'd appreciate hearing from you.

1. I'm looking for pictures of these antennas in-action.
2. How long are the (supplied) radials (just above/below) the top
two traps? (Not talking about ground radials).
3. Is the antenna self-supporting or do you guy-wire it?
4. When ground-mounting this antenna, i understand that you drive a
rod 4-8 feet into the ground and connect the antenna to that... but
how? Supplied connector? And then isn't the coax-feed point open
to water and other problems?
5. Is a matching network req'd like on the R6000? If not, why not?
6. Is this antenna truely a no-tune antenna for all the bands they suggest?
(ie: is a tuner req'd with this guy?)
7. How does it perform? On par with similar HF verts? (Don't compare
it with a tri-bander yagi or something!)

Thanks for taking the time to read my Q's and I hope to hear from happy
(and unhappy) 4/5-BTV owners! Reply to group or via my email
listed at QRZ.com.

There was a book made into a TV mini-series in the mid-70s:
"The French Atlantic Affair". It was pretty good, with a plot about
some downsized NASA folks hijacking a cruise ship.

Hero was a vacationing Amateur who brought his HF transceiver
along. As I recall, it was a Swan, but the resolution *still* could
have happened!

I don't know if it ever made it to video, but I couldn't find any
reference to it. They may have changed the title at some point.

Paul, you might want to consider insulated wire. However, generally speaking, you can probably get away with some contact with tree branches and still not suffer very much signal degradation.

Scott, typically a two element quad has and input impedance of 100 ohms when the spacing is about eight feet or so. Actually, you can adjust the impedance somewhat by varying the spacing. The 1/4 wavelength 72 ohm coax matching transformer is near ideal to match 50 ohms to 100 ohms. And you can't beat it for simplicity. I've used it with 1.5 KW without problems.

It has always been my opinion that a gamma match is overkill for a quad.

Harry, I think you will have a more efficient, predictable and simple system for both bands if you just had an 80m 1/4-wave vertical and bottom-loaded it for 160m.

You may intend to have a tuner at the bottom anyway. In which case the simple 1/4-wave 80m vertical will do very well also on 40m and 30m.

Download program VERTLOAD and/or LOADCOIL for design and location of loading coils in verticals.

Joe:

Thanks. Insulated wire doesn't cost much more. Unless there is some downside to using it, I will try stringing the insulated wire through the tree (s) and see what happens.

I would imagine (imagine=lack of knowledge) that whatever resistance is caused by the insulation is comparable to a year's worth (or so) of oxides on non-insulated wire.

thanks & 73

If using bare wire, or more likely, if the ends of the wire (bare)
are touching branches of the tree, is there any safety concern,
especially if Paul runs half a kW on the dipole? (in general,
not necessarily pine -vs- oak -vs- maple -vs- dead -vs- alive!)

It may be a bit rough on the tree, but I've seen HV feeders
brushing up against branches during a windstorm, with no worse
effects than some sparks. I wouldn't want to be standing near
the tree, TYVM. Now, if it had been an old, dead, _dry_ tree,
I suspect we might have had a fire to deal with.

In that case, we can put this to rest. After all, antenna ends are
likely not going to be hanging in mid-air next to some leaves...
more likely tied off on an insulator which would then be secured
to the tree or other supporting structure. Ya? And the weak of
heart can use insulated wire.

By the same token, the dry wood/leaves don't provide a very good leakage
path for either AC HV or for RF. I've been able to successfully burn up
traps, coax and insulators but have yet to set a tree on fire :-) Not
enough power, I guess.

This is going to be a monoband quad for 10m -- But, basically, I was asking if there is a better matching network, no matter how difficult to build (than the 1/4 wave section of 75 Ohm coax). I am aware of the different ways, but I just don't know which is the most efficient.

Scott.

I am thinking of putting up a G5RV antenna. The only problem I have is it would have to be strung up by my aluminum sided garage with the feed line running down the side of it. Can anyone tell me problems I might have with the aluminum siding interfering with the signal? Any help is appreciated.

1074. best wire choice for 20M loop?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-23 22:22:05 UTC
From: carkenord@juno.com
Message-ID: <4346b55e.0110231422.39e5e269@posting.google.com>
Source record: 155627

My 20 meter delta loop has been up for more than 10 years, and its starting to fall apart. Time to put new wire up.

This antenna is approx. one full wavelength ......in the form of an equilateral triangle. The base of the triangle is towards the ground, the apex of the triangle is up. The base is about 20 feet above the ground. Feed is via coax, with the feedpoint at the center of the base.

I live in Denver Colorado....with both smog and ice.

I have 3 kinds of wire on hand, and WILL use one of these 3 choices. I need input as to which wire to use. My choices:

1) 16 gauge stranded soft copper, insulated
2) 16 gauge solid soft copper, insulated
3) 16 gauge stranded, insulated....not copper, some kind of shiny finish

Which of the above wires would be best choice, from a structural/reliability/strength standpoint? Which would be the worst?

Which would be best from an "RF efficiency" standpoint? Which would be the worst?

From what I have stated, what would be the best wire.....overall.....the best compromise?

A total of 5 questions that I am wondering about. Please help me out.

Thank you..... Lee Carkenord KA0FPJ

1075. After-market Antenna for Yaseau VX-5

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-23 22:22:34 UTC
From: gfirenzi@yahoo.com
Message-ID: <dc589273.0110231422.32bd4012@posting.google.com>
Source record: 155628

I know this question has been asked before, but I'm still fuzzy.
There must be some idea as to what the best after-market replacement
for the "rubber ducky" antenna would be. I'm tempted to purchase the
Pryme AL-800 for my Yaseau VX-5. Someone has told me that this
antenna will probably stress the radio antenna connection. Is this
true? Pryme makes a high gain thin wire antenna that might be better
suited for my HT. Any ideas?

Thanks,
Guido

Could I take a 1/4 wave of wire and wind it into a coil and use that as
the stub element??? Kind of like a loading coil as a match, huh? I've
heard you can do that kind of thing with ground plane radials so why not
as a matching coil stub.

I'd go with the solid copper, insulated, with adequate supports, of course. But that's just me. The stranded would carry more current at higher frequencies, and may or may not be as strong. If you don't know what the metal is in the third, I'd stay away from it.

I used aluminum electric fence post wire for my inverted V.. got 1/4 mile of it for under $20, and I still have alot of it left.

Just my two cents

I saw some Rabbit ear type set top tv antennas in Radio Shack, with adjustable booster.

Do they work ? I mean are they better than rabbit ear w/ no amplifier ?

I'm no engineer, but based on lots of practical experience
with rabbit ears, anything other than the
basic rabbit ears is not likely to make any significant
difference. I wouldn't waste the bucks on a gimmick like
some of those that they used to put on rabbit ears.
Hope this helps.

In a word, no.

The main limitation of rabbit ears, is that they are not very directional, and so you will often get double images or "ghosts" when the same signal arrives at a slight delay because it bounced off something. You can fiddle with rabbit ears to minimize ghosting, but you have to do it for each channel.

An amplifier does not correct that problem.

There are miniature directional antennas with amplifiers that might be more directional than rabbit ears. They look like a flying saucer and are intended for RV's.

Has anyone any good ideas on homebrewing a variable
capacitor for small transmitting loops. The voltage is very
high, and the capacitor must withstand voltages in
the 1 to 5 KV range. The maximum capacity should be in the
order of 50 to 100 pf. Thanks for any suggestions including
practical construction details or helpful hints.

The answer is no. The real reason, is that if you have poor reception to
begin with, you will simply have -amplified- poor reception with the
amplifier. In other words, if you need the amplifier, it won't help. -Dave

I spend most of my mobile 2 meter time on simplex so I am always looking for the best mobile antenna I can find.

I recently bought a 2 meter Anntron Colinear antenna for about 20 bucks because I wanted to check out the advertised "an Honest 6 db gain".

Anyway, it is now mounted on a stake mount on my pickup truck. It seems to receive MUCH better than any other antenna that I have used. I am getting good signal reports that seem to indicate that it performs better than the 5/8 wave antennas that I have always used in the past.

However, the SWR on it is very erratic. I can get the whip adjusted to give a decent (flat to 1.2) match over a couple of Mhz but its very jumpy (varies dramatically as the whip sways).

Anyway, I was just wondering if anyone else had experience with this or other colinears and had an opinion. Do they really have 6 db gain and are they signifigantly better than a 5/8 wave?

Dave,
As it was explained to me, and made sense, is that when the antenna flexes it changes the interaction with the vehicle thus changing the SWR. With longer antenna's you can expect more flex and thus more variability of the SWR.

How much variance are you seeing? If it is still under 1.5:1 there is little cause for concern.

Maybe a "trombone-like" capacitor like you use
in some gamma matches? **VERY** easy to make.
Strip the shield and outer insulator off of some coax,
leaving the center conductor insulated. Slide the
insulated center conductor into a piece of metal
tubing that fits closely. The tube forms 1 plate
of teh capacitor, and the center conductor forms
the other. The amount of coax in the tube determine
the capacitance. Cut the tubing for the maximum
capacitance you want, and make the center conductor
a couple of inches longer.

Hi,
some ideas should be in the following articles - see
http://www.qsl.net/dj3tz/kondens.txt . I think the simplest
construction is the trombone-like one: two pairs of tubes going
tightly one into another, separated by a teflon foil. In fact it is a
pair of variable capacitors in series, so it should withstand fairly
high voltages.

It is bad practice to use coax cable as tuning capacitors for
magloops. The resistance of the THIN inner conductor is in series
with the capacitance. The Q of the whole loop is reduced.

So some of the advantages of using copper pipe for the main loop
are lost. The effect would be reduced if the coax was used only as
a trimmer in parallel with a large fixed-plate capacitor.

Regards, Reg, G4FGQ

If the GSM base station antenna were to come loose and fall down, it might strike a human being on the head, thereby causing minor injuries.

How tall is it? Is the 6dB- 6dBd or 6dBi? If this is the same company that
makes the CB antennas, their gain claims are fiction.

Hi

I'm looking for any kind of information about antennas for GSM base
stations: what kind of antennas exist ? for what use ?
I'm also looking for economical and ecological information about these
antennas.
What can be the danger on human beeings if they live near a base station
antenna ?
Every information can help me.
Thank you

Julien

Tim, N6DRA/4 wrote:
"The Editors and Engineers Radio Handbook recommends away from dipoles for 6M. The launch angle is not suited."

Launch angle depends on antenna height. One of the antennas pictured in Tim`s attachment is a turnstile (crossed dipoles).

My W6SAI Radio Handbook says:
"Generally speaking, horizontal polarization seems to hold a slight edge over vertical polarization for long distance vhf communication and construction problems seem to be less with horizontal elements when a large antenna array is assembled."

The statement above is weak as water as it should be if it was to be included in the book at all which it probably should not have been.

Best regards, Ricjhard Harrison, KB5WZI

"Do you know a source for basic run-of-the-mill paper cones?"

Yes, I want to know too. My Atwater Kent Model 40 needs speaker repair and could also use a tune-up. Do you know of a source of service information and schematics? I lost my N.M. Beitmam: "Most Frequently Needed Diagrams" many years ago.

Best regards, Richard Harrison, KB5WZI

I don't know if the values are right, but Ten Tec sells the variable capacitor
from its antenna tuner in kit form -- I think it runs about $49.

Tim, N6DRA/4 wrote:
"The launch angle is not suited."

I agree that grounded vertical antennas tend to launch signals parallel with the earth and at low elevation angles while horizontal antennas tend to launch signals which cancel at low elevation angles due to the out-of-phase earth reflection of the horizontally polarized signals at low elevation angles.

If you have any air gap at all between the teflon and the metal,
it tends to arc at very high voltages like 10KV. This
is the biggest problem with "permittivity tuned" capacitors.

Gamma matches operate at low voltages, so they don't have this problem.

Maybe you're at a low enough voltage that you'll get away with it.

Hi to all...

I am planning to put up a vertical this winter for 80m. I have an aluminium pole of about 13m high, and I would load the base with a coil to adjust for minimum SWR.
The key element is... RADIALS! I took a piece of "left over" 40-pair telephone wire (30m long) and soldered all inner conductors together on one side.

My question is: which would be better:
40 radials each 30m long
or cutting it in half, giving:
80 radials each 15m long...

Looking forward to the expert's opinion hi

Go to http://www.imdb.org and enter in the search Amateur radio, there are
138 movies with amateur radio, here are the top 10:-

1. Fairylogue and Radio-Plays, The (1908)
2. "Acme Radio Hour" (1995)
3. Automatic Radio Compass: Part I, The (1955)
4. Automatic Radio Compass: Part II, The (1957)
5. Representative Radio (2001)
6. Radio Rampage (1944)
7. Radio Rhythm (1929)
8. Radio Rhythm (1931)
9. Radio Riot (1930)
10. Radio Riot (1949)

1114. New Program - Skin & Proximity Effect

Source record: 155667

NOW AVAILABLE ** Small program "WIRESKIN.exe"

This simple program demonstrates the effects of the increasing resistance of copper conductors as frequency varies from DC up to 1GHz or more. As examples it computes performance of a straight round wire, an open-wire transmission line, of any sizes and dimensions, and a half-wave dipole. The effects of performance versus temperature are included.

See how fast the HF loss of balanced-pair lines increases as the wires get closer together and Zo decreases. Loss can be greater than coax.

Use the program to calculate the loss at speech frequencies of a Victorian 400-mile overhead phone line, London to Edinburgh.

Or of a twin 1" diameter, spaced 10 feet, 100 mile power transmission line at 60Hz. Did you know skin effect begins at power frequencies? Or compute loss of 100 feet of 75-ohm line at 21 MHz. Or calculate Q and bandwidth of a 1/2-wave dipole at 144 MHz. End-effect included.

As a sideline, convert kilometres to miles, mm to inches, or degrees Celsius to Fahrenheit.

Only one file. 40 kilobytes. Not zipped up. Run immediately. Download WIRESKIN in a few seconds from site below.

Irv:

You can create very high voltage caps using glass as the dielectric. There is an antenna tuner in the current issue of the ARRL Radio Amateurs Handbook which uses inexensive picture frame glass. An estimated breakdown voltage of about 12,000 volts was obtained this way.

I saw another article in which a regular air variable cap was used, with labratory glass slides slipped between the rotor and stator plates. The glass dielectric actually has 2 benefits; increased breakdown voltage and higher capacitance due the the dielectric constant of glass vs. air.

The mechanical details of making a glass dielectric cap variable can be overcome in a number of ways. An article in Electric Radio Magazine a few years ago, also about an antenna tuner, used a screw mechanism to create linear motion to move the "rotor" plate of the glass dielectric cap to increase or decrease capacitance. If you wanted to get fancy, you could motorize such a mechanism and control it remotely.

Hope this gives you some ideas.

Hello,
is there a possibility to avoid 1:1 or 4:1 balun when connecting a 50 Ohm coax line to a halfwave dipole(e.g. for 14 MHz) by simply (close to the connection point) adding a e few loops (OD 25-30 cm)of the feed line-coax?

Jan,

It is not advisable to try just the turns of coax.
There are many good reasons to use Ferrite beads as close as possible to the end of the coax.
One article you might want to read is at URL:
http://fermi.la.asu.edu/w9cf/articles/balun.pdf
You likely can build your own balun for a 1:1 with the proper type and amount of ferrite beads.

A simple search in Google using "GSM base station antenna" turned up
almost 10,000 hits. Surely you can find some info there. Generally,
the RF field off-axis from such antennas in operation is rather
low...the companies that use them place a pretty high value on the RF
they radiate and don't want it heating the ground under the antennas.
I personally wouldn't worry much about it, but surely you should make
up your own mind about that. (I would worry much more about the field
from mobile transmitting antennas an inch or two from my head...)
Again, a search using a web search engine or a magazine article search
engine should turn up LOTS of articles about physiological effects of
radiation in the 1-2GHz range. I'd be very surprised if you didn't
find a lot of conflict in the conclusions drawn by different studies
and authors.

Cheers,
Tom

...
Something to be careful of is corona. If you replace say 90% of the
thickness of air by glass, but leave the remaining 10% as air, then
indeed you'll increase the capacitance. Effectively you'll have an
air dielectric cap of 10 times (1/0.1) the original, and a glass
dielectric cap of 1.11*k* the original, where k is the relative
dielectric constant of the glass you used. For example, if it was a
100pF air cap, and you use glass with k=5, you'd end up with 1000pF in
the 10% air and 555pF through the 90% glass part. The net is 357pF,
which is a nice gain. But...what about voltage rating? If the
original was rated at 1000V, assuming it's because of the field
between the plates and not high fields around any sharp edges on the
plates, then with all air, it was a uniform field between the plates.
But in the new 90% glass cap, you have 35.7 percent of the voltage
drop across the 1000pF air gap and the rest through the glass. Since
the air is only 10% at thick as it used to be, but has 35.7% of the
voltage drop, you better DERATE the capacitor voltage to
1000V*0.1/0.357 = 280 volts!

This is a somewhat simplified analysis, ignoring the high fields
around the edges of the plates, but it illustrates what can happen.
In fact, air in high voltage film caps and in high voltage
transformers can cause the same sort of trouble, leading to early
failure. One way around this is to find a liquid or gas which is a
good RF insulator and has high dielectric constant. Some oils are
pretty good that way, though can be really messy to deal with if
you're trying to seal up a variable cap. Note that the same thing
happens with Teflon-wrapped copper tubing or using the inner conductor
of coax. One advantage in a coaxial configuration if you have a solid
dielectric in intimate contact with the inner conductor, is that the
field in a coaxial cylinder capacitor decreases as you go out along a

radius from the center, though that's not a huge effect unless the inner to outer conductor diameter ratio is large.

This effect generally isn't a problem in DC applications, because any corona will quickly charge up surfaces and take away the field that caused the corona. But in AC, from 50Hz on up, it's a serious consideration.

Hope these thoughts help some!

Cheers,
Tom

1126. Ceramic line spreaders- glazed or not?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-24 23:21:16 UTC
From: Crazy George <munschNO@attglobal.net.SPAM>
Message-ID: <3bd753e8_2@news3.prserv.net>
Source record: 155581

Group:

Here is a materials question. I have been using and occasionally breaking some of the 6" white ceramic (steatite?) 600 ohm line spreaders made by Johnson, Birnbach and others. I recently bought several 6" spreaders at a swapfest for replacements, but these don't seem to be glazed like those I have been using, as they do not exhibit the shiny glass surface characteristic. There is an impression on one side of the body with poorly defined lettering "JOHNSON" which is different from the old Johnson examples I have, and does not include the part number which is part of the old impression. Does anyone know if Johnson or its successor is actually producing these, or are they counterfeit? And more importantly, are they water proof? The reason for my concern is that 50 years ago when I had trouble finding decent glazed insulators, I tried to use some of the old white ceramic bars which were used in pre-war knob and tube electrical house wiring to hold 2 or 3 single #12 wires running parallel to each other. The two screw holes in them provided useful wire attachment points. After a few months of exposure, the one at the far end of my antenna which was attached to a steel windmill tower conducted well enough to ground to light a 40 watt light bulb to full brilliance when the other lamp terminal was connected to the AC line. Then I understood why I was having trouble loading the wire on 75 meters. As these were not glazed, I have since avoided unglazed ceramic for outdoor use. Or is the glazing on these new examples waterproof but not shiny? Is that even possible? Ceramicists to the rescue, anyone?

You'll get plenty of opinions, of course :-)

Ideally the radials should be 1/4 wavelength, or 20 meters, up to a maximum of 120 radials.

But few reach that "ideal." Probably either combo would work OK, but if I had the room, I'd go with the 40 radials at 30M.

Coax Switch - Five Position - Like New - Ebay

This switch is in excellent condition. I bought it at the Dayton
Hamvention. It doesn't look like it has ever been used.

For auction on Ebay, click on:
http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=1288836016

I will be glad to provide additional information, or send more detailed
pictures to your email address. Contact me at w4tq@mindspring.com

1130. Tips on assembling and aligning a beam antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-25 00:04:48 UTC
From: tek_guy@hotmail.com
Message-ID: <cbf4a67d.0110241604.b501496@posting.google.com>
Source record: 155583

A couple of days ago, the Cushcraft 6 meter 3-element beam antenna that I ordered arrived, and I've almost finished it. I've gotten to element attachment to the boom, and I've run into a problem: I'm having a hard time aligning the director element with the driven and the reflector elements, and making the director parallel to the rest. My question therefore is in two parts:

First, does anyone know any "tricks of the trade" for keeping beam antenna elements spaced correctly, and to make sure they come out looking parallel in the end?

Second, if I can't get the elements aligned perfectly, does it matter?

Thanks for any help...

73s,

Jim

Use 40 radials each 30 meter long.

Radiation resistance will be better and base loading coil will be smaller.

==========
No problem at all. Just keep the feedline crudely 1 inch away from the garage aluminium walls for much of its length and nobody will notice any difference.

But don't get stuck on a G5RV. It is no better than any other multi-band dipole of crudely the same length. If you use a long coax feeder at the transmitter end it is definitely less efficient than the average multi-band random length dipole.

Download in a few seconds program VARNEY from website below to analyse performance of any sort of centre-fed dipole antenna and feedline system. It will also give you coil and capacitor component values for an L-matching network to 50-ohms.

1136. More on 2 meter colinears - A project!

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-25 04:13:43 UTC
From: Dave <dalden@home.com>
Message-ID: <CBCA575380EDA1F2.A38E7233FC33912A.25046CB89570A657@lp.airnews.net>
Source record: 155589

I've kind of become fascinated with this colinear stuff. I found a project on the following site:

http://home.online.no/~sondred/Colinear.htm

However, it is in Norwegian or something and I can find any engine to translate it. If anyone knows where it can find details about this project in English I would sure appreciate it an I would very much like to build this beast.

I guess that I'm particularly interested in the 6db gain to be had from an omnidirectional antenna. This, if true, is as good as a small beam.

Thanks,

Dave KB8VJD dalden@home.com

This is reasonable and should work well.

> Mount two 102" stainless steel CB whip antennas horizontally near the
> top of the mast, one pointing rearward from the motorhome, and the
> other pointing to the side, away from the motorhome. These then
> become part of the ground plane.

The roof is a very good groundplane. I don't think you will benefit much from the whips. Better might be some radials down to the chassis of the motorhome, say at the corners, and temporary radials to lay out on the ground. I would consider running a loop of wire under the chassis and using that as the base groundplane, attaching a few bonding jumpers from this loop to various points on the chassis.

Another approach is to get an auto-tuner like an SGC or Icom AH-4. Mount it on the roof. Make a tip-up or telescoping pole to use as the radiator. Texas tower has telescoping diameters of aluminum tubing. Seems to me that 20 feet is enough to make the tuner work on 75, and would generally work better than a screwdriver. I have both, and the screwdriver is superior on 3.5 and 7 mhz when the length is short like 10 feet or so, but as the whip gets longer (or the frequency increases) the difference disappears. The autotuner is a bit easier to use than the screwdriver. Also, a random wire can be thrown into the trees (look at the slingshot type launchers) and it will outperform the 20' pole.

Incidentally, it is a bit tricky to tune a screwdriver you cannot see since you might move it the wrong direction. I solve this problem by using a 2-way coax switch that attaches the feedline from the screwdriver either to the rig or to an MFJ antenna analyzer. This way I can find the resonant frequency of the antenna and quickly move it to the right frequency without even transmitting. Works great for stationary use.

Source record: 155593

I've used 1x3 lumber. Drill holes at the proper points on the
1x3's and slide the elements into the holes - you need to
do this on both sides of the boom, with the element to boom
mounting loose. You *do* have to make sure the 1x3's are
parallel. Once that's done, the elements will be parallel and
properly spaced (assuming you spaced the holes in the
1x3's properly). Next, you have to make sure the elements
are at right angles to the boom before tightening the mounting
hardware.

To make the holes, first make the 1x3's long enough. Butt
2 of them together, and screw then into a piece 4' long
so 2 feet overlaps each of the 1x3's. You need to do that
twice. Next, clamp the two "manufactured" long 1x3's
together. Measure carefully to locate the holes, and drill
both "manufactured" 1x3's at the same time. While still
clamped, use magic marker to label both of them with
FRONT so you don't end up with one of them flipped
end for end when adjusting the elements.

Now, if you are using thin, tapered elements, you'll
need to slide the 1x3's closer to the boom. You want
the drilled holes to be just slightly bigger than the element
diameter at say 4' from the boom.

Source record: 155591

I solved this problem on my SUV by having a local welding shop install a 1.25 inch receiver sideways behind the rear wheel just below the wraparound bumper there. It is welded to the side of the trailer hitch receiver support (mine has closed end tubes so I couldn't do the simpler trick of sliding a square tube inside the receiver tube). This provides a strong mount that has no interference with the tailgate or the trailers I tow. I put the mount flush with the edge of the bumper. With the High Sierra 1.25" mount this places the antenna about half a foot to the driver's side of the vehicle. It does not stick out as far as the rearview mirror. Putting the coil and lower section too close to the body does cause losses, so you want it out as far as is safe. The vehicle code I checked indicated that protrusions from a vehicle should not exceed one foot, this is well inside that.

I assume the feed line you mention is the 300 ohm balanced line, in which
case its sufficient to keep it at least 5-10 times the spacing of the
lines away from the aluminium. As far as the antenna itself, aluminium is
low loss and will affect the antenna's radiation pattern in some way
rather than waisting power. But usually we can't avoid this problem...

Good luck!

1141. Porcelain Insulators

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-25 05:39:19 UTC
From: richardharrison@webtv.net
Message-ID: <19575-3BD7A587-97@storefull-111.iap.bryant.webtv.net>
Source record: 155594

A question regarding suitability of unglazed ceramic insulators was raised by Crazy George, I believe, though I can`t find it now. I believe he had tried some outdoors and they seemed lossy when wet.

Maybe specifications for a-c power distribution would indicate suitability. I had never thought of not using real porcelain insulators outdoors until I saw some rough white plastic insulators in a store much like Radio Shack.

Lincoln`s Industrial-Commercial Electrical Reference did have something to say in its outside wiring section for voltages between 600 volts and 2500 volts concerning insulators:

"Insulators made of porcelain or other material approved for the purpose must be employed as supports for open wiring over 600 volts but not exceeding 2500 volts"

The electric power company here has been replacing distribution lines in neighborhoods nearby and I notice all their insulators for whatever voltage are porcelain. The only difference I see from the older insulators is that they are now all made in Brazil. For higher voltages the insulators get larger and more of them are hooked together to make longer strings.

Lincoln`s "but not exceeding 2500 volts" just indicates that higher voltages are covered by a different specification. All the very high voltage insulators are porcelain too, as far as I`ve seen.

What is porcelain? It is defined as a vitreous, more or less translucent ceramic body or ware (china for example). The glassy surface repels moisture. Without the glaze, I don`t think a ceramic qualifies as porcelain and is likely to be trouble as an insulator wetted with impure water.

Best regards, Richard Harrison, KB5WZI

From: "David J. Windisch" <davidw@copper.net>
Message-ID: <z0SB7.54$bb1.34526@newsfeed.slurp.net>
Source record: 155597

I posted a similar msg to anothe group, and now this one, to get a wide selection of ideas:

This week, I bought a house on the north end of a flat 1-acre "mesa" plot, at around 900' ASL, on old farmland. It's a long sad story .. for another time.

I can put up ALL sorts of verticals, towers, etc. without wife, neighbor, airport, or zoning interference. I'll get permits, naturally.

Because I have around 50000ft of #12 bare copper wire, I could run real radials for a vert or two.

The antenna conundrum is this:

I want to experiment anywhere within the ground-system area, a difficult thing to do with a standard-configuration radial system.

If it's a better thing to do, I'd prefer to install a grid of wires in the 130ft E/W X 200ft N/S field south of the dwelling, say, 65 wires on the shorter, and 100 on the longer, side, and soldered at all crossings. I'd use those foot-long spikes at the ends as hold-downs.

I can put ground-screens under any vertical bases.

This would define and stabilize the "local" grd under any antennas, vertical or horizontal, WRT feed-Z, lightning, whatever --- correct?

Is the idea good-bad-indifferent, and why, pls .. ?

TIA!

73, Dave, K3BHJ

1145. All band hf vertical

I am just a newbie. I have a butternut 6v, a five band I think. Is about 25 feet long with 3 trap coils and two capacitors with a coil at the feet point. Base is 10 feet off the ground.

From what I have been reading the concept of a multiband vertical is a fallacy. Basically, hf verticals are a one band (resonant antenna to the length of the antenna). It works better at that resonant frequency and progressively less efficient as frequency lowers. Any feedback?

Also have been studying radial wires. Literature is sometimes contradictory. It seems to me from the reading that the best length for radials is approximately the length of the vertical attenna with about 20-32 radials. Comments?

If you want it to self-tune, forget it. The rig will not tune the past the 40 meter band when the ATAS is active. You could run the ATAS all the way up manually, then use the rig menu option to tell it no ATAS, then run it into an LDG, SGC, etc. tuner and get it to "tune". But considering there is only about 3 feet of radiating element, it's efficiency would be pretty close to that of a dummy load.

I have tried this using an LDG tuner, and it wasn't worth the effort. A simple 75 meter hamstick will perform dramatically better...

Yes they work. But that should be qualified, better than what?
Better than nothing at all, yes. Better than an outdoor antenna,
probably not. Unless the channel you're interested in is local and or
very strong in your area, you will probably not be happy with rabbit
ears.

What? If you need an amplifier, you need an amplifier. Amplifiers
work just fine where implemented correctly. What you stated sounds as
if amplifiers are useless by their very nature for any reason... and
that would be just not true.

hey there
what i have done when assembling yagis was to drive a piece of pipe in the ground and have it stick up about 4-5 feet so its comfortable to work on then i would attach the boom to the pipe and then attach the elements then go to the end of the boom and eyeball for all elements being on the same level plane of cource you need to have the pipe you drive into the ground level and plum to start with but not tough thing to do
good luck

I wouldn't use it outside, due to UV exposure breakdown problems.
High quality cable might cost more, but in the "long run" it is worth it.
I suggest supporting your local amateur radio store for coax cable. They
likely carry high quality cables and can assist you in picking the right one
for you application.
If you don't have a local amateur radio store, I suggest the suppliers that
advertise in QST. The Wireman, Radio Works, and Cable X-Perts all have
proven themselves to provide enduring value for coax solutions.

Dave, K3BHU wrote:
Is the idea good-bad-indifferent, and why, pls..?"

According to Ed Laport, former Chief Engineer of RCA International, it is a bad idea to tie radials together beyond the immediate vicinity of the vertical antenna. It encourages current between radials which only produces loss. The current to be promoted is in the radial direction only.

Best regards, Richard Harrison, KB5WZI

1158. Antenna earthing

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-25 14:48:24 UTC
From: JKM <kerr@mclaughlan.freeserve.co.uk>
Message-ID: <9r98pd$bg1$1@news7.svr.pol.co.uk>

I posted this a short while ago but didn't get any response (had a few problems posting as well but that's another story). Is anybody able to assist or have I offended someone in some way?

Hi, I'm looking for a bit of advice regarding earthing of antennas. I have a tilt over mast system with various antennas mounted on a stub mast which is mounted in a rotator (Yaesu).The highest antenna is an Icom discone ,below this I have a Datong active antenna for shortwave listening, below that I have an elevator with cross boom which supports a 70cm X yagii on one side and a 2M X Yagi
on the other. I believe that everything from the rotator up is insulated from earth at the moment due to the fact that it is mounted on the rotator and supported in the rotator cage by an insulating bush. The cross boom is also insulated from the elevator motor. Should everything (stub mast, cross boom etc.) be earth bonded to a good earth point (an earth rod)? I'm also looking for advice on the mounting of the Yagi's but I'll leave that for another day.
Cheers
Kerr GM7CZU

|
|Maybe specifications for a-c power distribution would indicate
|suitability. I had never thought of not using real porcelain insulators
|outdoors until I saw some rough white plastic insulators in a store much
|like Radio Shack.
|
|Lincoln`s Industrial-Commercial Electrical Reference did have something
|to say in its outside wiring section for voltages between 600 volts and
|2500 volts concerning insulators:
|
|"Insulators made of porcelain or other material approved for the purpose
|must be employed as supports for open wiring over 600 volts but not
|exceeding 2500 volts"
|
|The electric power company here has been replacing distribution lines in
|neighborhoods nearby and I notice all their insulators for whatever
|voltage are porcelain. The only difference I see from the older
|insulators is that they are now all made in Brazil. For higher voltages
|the insulators get larger and more of them are hooked together to make
|longer strings.

My power company is a cooperative serving a nominally rural area. That means that it is relatively poor as power companies go. I have had no end of power line noise problems.

While I was helping train the untrained guy that they assigned as their 'noise-locating-expert' he let it slip that they had thousands of epoxy insulators in use. These were disintegrating in the Tucson sun and some had leakage currents is the 10 to 100+ milliamp range. I don't know whether this is wet or dry, since it's usually dry in Tucson.

As they do routine maintenance they are removing these and going back to porcelain. They gave me some of the old ones so I've had a good look at them. I am thinking of using them in the guy wires of my tower if I decide to shunt feed it for the low bands. The structural part is a fiberglas rod, captured inside the forged aluminum ends. The ribs are cast epoxy and are now crazed on the surface. I'm sure that when new they were nice and smooth and shiny.
|
|Lincoln`s "but not exceeding 2500 volts" just indicates that higher

|voltages are covered by a different specification. All the very high
|voltage insulators are porcelain too, as far as I`ve seen.

As I recall the line out at the road is 7 something KV.
|
|What is porcelain? It is defined as a vitreous, more or less translucent
|ceramic body or ware (china for example). The glassy surface repels
|moisture. Without the glaze, I don`t think a ceramic qualifies as
|porcelain and is likely to be trouble as an insulator wetted with impure
|water.

Yes, that is plausible. The rule of thumb, if I recall, is: distribution voltage is 1 KV per mile of distribution line, i.e. a 50-mile distribution line would likely have a distribution voltage around 50-KV.

It varies greatly by company. There's still old 4kv stuff and I suppose
there's 24kv but I've never personally encountered that. Our local
distribution is at 11kv.

On 24 Oct 2001 15:44:20 -0700, tom_bruhns@agilent.com (Tom Bruhns) wrote:
[snip]

Tom makes some really good points, that are not well-understood in the amateur (and sometimes the professional) world.

Some insulation (other than air) can be worse than no isulation.
|...
|Something to be careful of is corona. If you replace say 90% of the
|thickness of air by glass, but leave the remaining 10% as air, then
|indeed you'll increase the capacitance. Effectively you'll have an
|air dielectric cap of 10 times (1/0.1) the original, and a glass
|dielectric cap of 1.11*k* the original, where k is the relative
|dielectric constant of the glass you used. For example, if it was a
|100pF air cap, and you use glass with k=5, you'd end up with 1000pF in
|the 10% air and 555pF through the 90% glass part. The net is 357pF,
|which is a nice gain. But...what about voltage rating? If the
|original was rated at 1000V, assuming it's because of the field
|between the plates and not high fields around any sharp edges on the
|plates, then with all air, it was a uniform field between the plates.
|But in the new 90% glass cap, you have 35.7 percent of the voltage
|drop across the 1000pF air gap and the rest through the glass. Since
|the air is only 10% at thick as it used to be, but has 35.7% of the
|voltage drop, you better DERATE the capacitor voltage to
|1000V*0.1/0.357 = 280 volts!
|
|This is a somewhat simplified analysis, ignoring the high fields
|around the edges of the plates, but it illustrates what can happen.
|In fact, air in high voltage film caps and in high voltage
|transformers can cause the same sort of trouble, leading to early
|failure. One way around this is to find a liquid or gas which is a
|good RF insulator and has high dielectric constant.

Even liquid dielectrics sometimes have trapped gas. Because of the effects Tom describes, the voltage gradient across the gas bubble can be higher that the surrounding liquid. This little "spark gap" can break down, creating "partial discharge" (commonly known as corona). When this happens, heat is generated, sometimes generating more gas, that breaks down, creating more gas..... until something pops.

|Some oils are
|pretty good that way, though can be really messy to deal with if
|you're trying to seal up a variable cap.

One of our missile programs used a klysron amp that, along with a pulse transformer, was cooled and insulated with a silicone oil (Coolinal). If I would

have absorbed all of that stuff that was on my hands and clothes, I would have grown boobs <g>.

|Note that the same thing
|happens with Teflon-wrapped copper tubing or using the inner conductor
|of coax. One advantage in a coaxial configuration if you have a solid
|dielectric in intimate contact with the inner conductor, is that the
|field in a coaxial cylinder capacitor decreases as you go out along a
|radius from the center, though that's not a huge effect unless the
|inner to outer conductor diameter ratio is large.

I (my company) once bought some corona testing equipment from Biddle Instruments. As part of the deal, I took a one week short course there in HV testing. One of the other 'students' was a guy who owned a cable making company in Canada. One of his products was coax for HV power transmission. (If I remember correctly he said it was the Bahamas that get power from the US mainland via an underwater coax cable.)

In their cable, the dielectric was in intimate contact with the center conductor because it was extruded over it, but at the outer conductor/dielectric interface there were voids, or partial discharge sites. To overcome this, they coated the outside of the dielectric with a semiconducting layer.

The fun part was at the end termination. If you think about the cut end of a piece of RG-8, there are lots of little pointy ends of the braid wires that create great discharge sites. They developed liquid-filled connectors to overcome this.

As an aside, Biddle's shop looked like a cross between Frankenstein's and Tesla's labs. The equipment I bought could generate 50 KVAC stacked on 10 KVDC. The 100pF capacitor that coupled the test sample to the detector was about 10 inches in diameter and 3 feet long.

I could argue in defence of the Handbook statements, because they are correct in principle, but much more important is Richard's earlier point: you need to be using the same polarization as the people you want to work.

Newcomers don't have a choice about polarization, because everybody else got there first.

For local FM, polarization is almost always vertical. If you have ambitions to work some DX on SSB/CW, go horizontal because that's what everybody else uses.

Believe it or not, the best and most inexpensive all-round vertical is a simple mast, rod, whip or wire, which is about 5/8-wave at the highest frequency you wish to use it at. Height is not a critical dimension.

Load it at the bottom, L or C, or use a tuner. Depending on the ground characteristics you may need 8 or more shallow buried radial wires.

Good people,

I have a somewhat off-topic question, but I figure you guys are the experts, so I thought I'd ask. My question relates to installation of a yagi to improve cell phone performance.

My office is within 3/4 of a mile of the US-Canada border (US side). Often, my cell phone (which I use from the office as well as on the road) gets picked up by a Canadian base instead of a US base, and I get hit with all sorts of charges for roaming, etc due to the "international calls" that I made. I got tired of arguing with the cell carrier. Since the cell phone has an external antenna jack and uses the 850MHz and 1900MHz bands, I bought a 800-900 MHz yagi from Wilson International, set it up inside my office, and pointed it at a strong US cell tower. It seems to help. No more Canada-side roams; fewer drops due to botched hand-offs.

Now for the question, as I have it installed, the boom (1" square aluminum tube) is NOT grounded. Are there performance issues here? I assume that there are no lightning-safety issues since the unit is indoors, but that's just a guess. The boom is electrically connected to the coax shield which is connected to the cell phone, and the cell phone sits in a charger/speakerphone stand on the desk. The charger is fed by an ungrounded "icecube" 110VAC --> 13.6VDC power supply. My current setup is temporary since I wanted to be sure that this would solve the roaming problem first, but now that it appears to be working, I want to make the installation more durable and sanitary.

A secondary question, though not as important, relates to the 1900MHz band being "off-frequency" for this antenna. Any thoughts on this point? Tech specs say that the high band is 1850.04-1909.92 MHz (Tx) and 1930.08-1989.96 MHz (Rx), which is not exactly on a harmonic. At the moment, though, everything appears to work.

Is there a better way to attack the whole problem?

All coaching appreciated!

TIA!

Hi to all newsgroup i just wandering what should be my attitude if i want to work some new-ones on the contest.
My problem is that this time i don't have time for the radio and therefore i can't spent much time
the question is :
if i hear someone interesting for me , can i work him without doing the contest?
There shouldn't be any problem for the qsl
Do i have to do a log contest anyway and sent it also if I work few stations, but i'm not interested in the contest

No problem working DX that is in the contest even though you may not be contesting yourself. You will need to give the correct info during the brief contact which for this weekend's CQ Worldwide SSB HF contest is a signal report and your CQ zone number....

Since you will not be contesting (and submitting your scores) there is no requirement that you log any of the contacts you make....good luck and I hope you snag some " new ones "

You might want to look at the DX tips I have posted on The DX Page of the website listed below...they can be beneficial...

No - work them all! The contester will want an exchange like a serial number and some ops just give everyone a serial number 001 since they have no intention of sending in a score. Contests are a great way to work a lot of DX. Have fun - see you on CQWWDX this weekend!

Message-ID: <3BD9DC5F.43159700@dialpoint.net>
Source record: 155521

Outside of safety there is no need to ground an antenna operating above 100 mhz and not too many antennas need it below that frequency. As your antenna is inside a building there is no reason at all to ground it unless maybe the wall cube shorts out and puts the 110 volts on the phone somehow. Grounding it will not help the signal.

If the antenna is working for you that is fine. Many yagi antennas do not like to operate outside their design frequency range. Especially on the high end. YOu may be beter off if you get a coner reflector type with a broad band feed. It should have the front to back ratio that you need.

Thanks for the reply. I feel better now!

Re the corner reflector, I did a bit of research and was considering building one myself, but the Wilson unit was available at the store which had the cell phone antenna fittings and time was short, so.... Can a corner be built as a "dual band"? I appreciate that they are a bit less fussy than yagis and that they can have a greater bandwidth, so your recommendation has a lot of appeal, especially since the cell band is 100MHz wide. Can I just build a "tall" corner with two dipoles located one above the other and feed them in parallel? Seems too easy....

Any insights welcome! I know just enough to be dangerous to those around me! BTW, AT&T wireless actively discourages external antennas, and getting help or info from them has been difficult.

Throw away the "remote balun" box. (or try to get a Budweiser for it)
Preferably bring the ladder line all the way to the tuner....if not then use existing coax. Just join 'em where the "remote balun box" used to be.

Put a choke balun between tuner and rig. Do not earth the tuner. Put tuner as far from rig as you can (ie a long patch lead). I assume you use a separate SWR meter? If not then get one.Make sure you put it next to rig.

Ignore what any built in SWR meter says.

Wes,

I have several issues of the handbook. I used them for the various 432MHz antennas I've built. The handbook has all dimensions for the T-match for the 432 versions, but none of them seem have details for the 2 meter version. Oh, I suppose, I could try to extrapolate the 2 meter dimensions based on the published measurements for 432MHz, but that would be mostly train-and-error. I was hoping someone else had already done that - or at least has some mathematical formula that has been proven to be accurate.

Thanks for the suggestion.

Would have thought Al. kitchen foil pasted under the wall-paper on the Canada-facing wall would help. Bring it around the corners for a couple of feet. Use the mobile with its own antenna generally in the centre line of either of the two corners..

Your 850 yagi will NOT work at 1900 but all you need is a single rod/ move it around the corners for a good signal.

do not bother trying to "earth" the boom

Thanks for the idea. Hadn't thought about shielding the room. The "Canada wall" is probably 40% glass, making that a bit harder. I may try to study up more on the corner reflector antenna suggested by R. Mowery. That sounds simpler.

You might think about using the partially-aluminized film made
for application to storm doors, windows, and other glass sheets.
It would let you see through, but should reduce the RF levels a
bit, at least.

Joe Jones <joejones42@hotmail.com> wrote:
: Thanks for the idea. Hadn't thought about shielding the room. The "Canada
: wall" is probably 40% glass, making that a bit harder. I may try to study up
: more on the corner reflector antenna suggested by R. Mowery. That sounds
: simpler.

Well, yes, but that direction that experiences the deficit might be
straight up or straight down, in which case you can still have an
omnidirectional pattern, with gain, in the horizontal plane.

That of course is how gain-type vertical antennas get their gain,

> >
> > No one has yet mentioned "Independence Day." Hmmm...

Geeze.."Depends Day" was a "B" grade movie made by Saliva Sally and Wrong
Way...She still resides in a dental rental in Hiram, Georgia. Sally Saliva
holds a Novice ticket and can often be heard (illegally) in the General
portions of the Ham bands.
Sally and her latest love, The Enjunear, are often heard bouncing around the
220 MHz areas of the Novice Band...they use this band to coordinate stops at
the local liquor stores and check-cashing outlets.
Saliva Sally has made at least one movie for which she is most famous.
For more information about Saliva Sally's movie, look at Mike's Package
Store agenda for show times.
Now we have to determine if she is "Sally Saliva" or "Saliva Sally". Only
Wrong Way knows for sure....

1187. AM antenna inquiry

Don't laugh. Please.

Specifically, what's the easiest way to improve AM reception?

"Portable" radio, not a stereo receiver with ferrite antenna.
Mostly for the evening.

CCrane has some AM antennas. Worthwhile?

TIA

1188. Still looking for that "perfect" antenna tuner

Im sure a lot of u will remember my earlier post concerning the Johnson Matchbox. Well Im still looking for a tuner that will meet my needs and not snap crackel and pop at high power levels as well as be versitle and reliable. My main concern is being able to transition from unbalanced to balanced on all bands using a single antenna fed with window line. I ran across this tuner and wonder what u antenna experts think. Please check out this link.

If you're simply trying to make a weak station stronger, and the station is in the clear with no interference, the Select-a-tenna tuning loop from Crane makes a dramatic difference.

From what I've heard, and seen on the web, (I have not had my hands on one), I would recommend that you NOT buy one until you have seen one up close, and inside. THe case is plastic, and, with the controls where they are, you need to use both hands to tune it.
The Ameritron ATR-30 is a MUCH better buy.

1193. 1/4 wave 2m Groundplane

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-27 13:53:19 UTC
From: Van DeWald <dewald@bellsouth.net>
Message-ID: <3BDABC4F.11FD4A4@bellsouth.net>
Source record: 155546

Hello all,

I'm interesting in building a 1/4 wave 2m groundplane antenna, by attaching pieces of copper wire to an SO-239 chassis, and then bending the radials down at a 45 degree angle. Just want to play around a bit, to see what kind of performance I might achieve. Ok, it's a boring Saturday, and I have more than enough stuff to do, but I'm new to hamming, and thought this would be a fun way to spend the day. Question, how much power can I safely put through an antenna like this?

Thanks,

Van

> with window line.

I had the same problem and solved it without a tuner box. I have
knife switches mounted in my hamshack window that allow me to
vary the length of my "450" ohm ladder-line from about 85ft to
about 110ft in one foot increments. That tunes my 130ft dipole
to an SWR less than 1.6:1 on *ALL* HF ham bands with no tuner
box required.

There are a number of reasons to consider such a tuning method.
1. No expensive tuner box required for high power (my reason)
2. Allows built-in autotuners to match the antenna system without
having to resort to an external tuner.
3. No tuner = no tuner losses
4. Balun/choke sees close to its designed-for impedance. (In my
antenna system, common-mode currents are minimum at lowest 50 ohm
SWR.)

If an interfering station's signal is arriving at right angles to the
desired station, it still makes quite a difference. The Select-a-tenna
has a figure-8 response.

That was probably my web site that was lost when I changed ISPs.
If I can get up the energy, I plan to do a new web page.

I recently worked a pile of people on 10m. SOme were running 25 watt mobiles, others were using 100+ watt base stations and yagis. The 2 loudest people on the band were running 50 watts and delta loops about 15-20 feet in the air. I use one on 40 and it is a hot performer. Try one.

It should be good for much more than you will need on 2M, unless you go in for Moon-bounce. I used one , hanging from the light fixture in my room, for my first non-rubber-duck 2M antenna- worked great at the 50W level.

van
i would sugest using some other wire other than copper its to soft the
first good wind or stary bird will bend it all to hell
go into your closet and snag 5 wire coat hangers the cheap thin ones not
the big heavy ones cut and straighten them and sand off the paint where
you need to solder and make sure you weather proof when your done and
also make sure you bend the radials to around 45 degrees
and the performance of this antenna we be greatly affected by how high
in the air you get it the h9gher the better and also how good of a piece
of coax you will use
have fun what a good way to spend a saturday
when your done with that try building a 300 ohm twin lead Jpole then
compare it to the ground plane

I have some white geniune parachute cord - I cut it off a used military
parachute myself in the early 60s- which has been holding up antennas
for over 20 years and is still intact and flexible.

Probaly more than you can get to the antenna. The so239 should be good
for around 1 kw. The wires should be also.

Wes,

Thanks for the offer. Someone else on the newsgroup sent a copy to me last night. I guess it's time I purchased a new version of the handbook. Mine is several years old.

Thought I might try building the copper tube jpole that I found in the ARRL Compendium book 4, constructed with 3/4 and 1/2 copper tubing, soldered together. Has anyone tried this? It seems pretty simple, and again, I'd place it in the attic,

Van

i hate to see anyone put VHF antennas in the attic its hard enough to get
signals to get where you want them when they are outside let alone in an attic
that is surrounded by metal straping and wires and nails not to mention the RFI
problems you will have getting into the cable and the telephones
the copper jpole works well for an omni directional antenna i ran one for awhile
at about 60 foot
if your in a deed restricted area try making a ventenna or a weather vane
antenna both can go on the roof with no worries from the neighbors

I just sucessfuly installed a 10 meter dipole 32 ' to peak worked out
really well.
did have to shorten it a bit center freq 28.500 guess it had something
to do with being in attic.
no tvi at 150 watts. ran into a few of the contesters on 10. made the
trip from nc to calf and down into south america no problem with5-9
reports.

1215. Advice on Aprtmnt Roof Mounted Antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-28 00:56:50 UTC
From: Curtis Bidulock <curtis@bidulock.com>
Message-ID: <mJIC7.4710$Nq1.561635@news-rep.ab.videon.ca>
Source record: 155568

I am looking for any advice, suggestions, or past experience with expanding range by mounting a tripod on the roof of a 3 level apartment building. I have approval to mount almost anything, within reason of course. I currently have a 5/8 mobile dual band on the roof right now which has greatly increased my operating distance but am interested in possibly mounting a dual-band ringo on a tripod and/or possibly a small 3-element yagi w/ rotor. Has anyone out there had past experience with a setup of this nature. I am trying to decide if the dual-band ringo would give me enough of an improvement over my mobile whip to bring in the weaker stations or would a yagi be necessary. Any advice is much appreciated.

1216. Elevated vs. ground-mounted verticals

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-29 13:50:18 UTC
From: vtail@hotmail.com
Message-ID: <3bdd5ce9.8367287@news.netis.com>
Source record: 155505

I believe I read in the ARRL Antenna Book that an elevated vertical (I think the figure I saw was at least 1/8 wavelength at the base) with from 4 to 8 radials of 1/4 wavelength each, works as well as a ground-mounted vertical with 120 buried radials of at least 1/4 wavelength each.

Does that sound right to you?

Do any of you have personal experience with elevated vs. ground mounted verticals?

I have a Butternut HF-2V that I was planning to ground-mount for 80/75 and 40, but it would be easier to elevate it 30 feet or so and run at least four 1/4-wave radials on each band ... as long as performance is likely to be comparable.

Thanks...

Rick WA1RKT

Hi,

I have an Icom AT120 auto-tuner, a marine version of the AH series and somewhat older than the AH-4, which I use with my IC-746. I wonder if anyone has used an AH-4 or similar Icom tuner with a Delta Loop antenna and if so, how did it perform?

SGC's manuals on their Web site show their Smartuners being used with dipoles, loops and squares, one side being fed from the normal antenna stand-off insulator and the other side from the ground terminal, there being no real "ground" attached to the tuner in this configuration. I can't see any reason why the SGC would work and the Icom not but I'd be interested in hearing of other's experiences.

TIA,
--

Source record: 155470

In the past MFJ has had connector problems. The 948 tuner I bought had connectors that would not screw on with out some difficulty. YOu might discuss this problem with the people you bought it from. If you don't mind replacing the connectors yourself, MFJ might just send you the connectors. They do seem to have a quality control problem. BTW the tuner I bought also needed to have several screws tightened up inside it.

I am not sure of the MFJ service now, but about 8 years ago I bought a TNC from a dealer at a hamfest, It seemed to be defective. I called him and was told to ship it back to the dealer and MFJ was going to send me a new one. In just a couple of days (the time it took for the ups truck to get here) I had a new TNC that was shipped from MFJ.

Brent,

The output from the AH-4 is made for single wire only. You could use a balum on the output but that would not be a great idea.
The more ground you can put in the better. It depends on what kind of earth you are on also. Sandy earth requires more ground rods. You may also have better luck if you don't make the wire lenght so close to 40 meters 1/2 wave. Make it about 10' longer and let the tuner make it happen for you. Your antenna is what is called an 'L' shapped configuration. If you were to put down about 12 wires on the ground, around the AH-4 about 65' long you will see a great improvement in your signals.

Get a copy of the ARRL Antenna handbook and this will help you to get better results for sure.

Good luck with it and have fun....

I have had the AH-2, a predecessor, for about 5 years. Its been worked hard for most of that time on all bands. It has handled 99 percent of all the many random wire inverted-L and T combinations I have thrown at it from 160m to 10m.

As a precaution there is a 450pF variable capacitor and a 5 uH coil to be connected by alligator clips in series with the antenna wire should the rare need arise.

The relay contacts must have had millions of operations with 100 percent reliability. Transceiver mainly the 100 watt Icom 735.

Hi Jim,

Your speculation of increasing efficiency by the folded di/monopole approach does offer the prospect on the surface of it. However, at this scale, the loss is generally in the ground and not the metal. Folded designs do nothing to change the amount of current going through that loss.

This is a transformer approach where you are matching the source to the load. The load has not changed except now you view it through a transformer. This transformation satisfies the source which now sees a new resistance value more aligned to it; but once the excitation makes it through the primary's transformer action, the load side (transformer secondary) still splits the power into radiation and loss in roughly the same familiar ratio with roughly the same familiar efficiency.

The multiplication, by the way, is related to the number of drops; but equally so to the ratio of the diameters of the driven line and the load line. In the ARRL Antenna Compendium, volume 2, there is a very good article entitled "Vertical Antennas: New Design and Construction Details."

In this they reveal the following generalized observations into the ratio of the main element diameter to a single drop element diameter:
1:16 60 Ohms (2:1 delta)
1:5 75 Ohms (2.5:1 delta)
1:3 90 Ohms (3:1 delta)
1:1 105 Ohms (3.3:1 delta)
3:1 140 Ohms (4.5:1 delta)
7:1 220 Ohms (7:1 delta)

There are a world of other variables (like the standoff between the drop and the main), or the actual size of the elements (diameter, aside from their ratio) that blur these numbers. However, the rough chart above reveals the underlying pattern.

Nobody mentioned the 1996 movie "Phenomenon" with John Travolta. In it, co-star Forest Whitaker plays a ham who transmits out of band to a military installation after the Travolta character decrypts some super-secret code in his head. Of course, the feds show up the next day and arrest them both. The synopsis for the movie is at:

1225. 2 meter 3/4-wave performance on 6m, 70cm?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-29 19:00:46 UTC
From: tek_guy@hotmail.com
Message-ID: <cbf4a67d.0110291100.31bc08ce@posting.google.com>
Source record: 155477

In the interim before I get my 3 element beam up for six meters, I'll need a temporary vertical antenna for monitoring, working DX openings, etc. I'd also like an antenna for increasing my HT's range on 2 meters.

I've heard that a 5/8-wave vertical on 2 meters will also work as a 1/4-wave on six meters; would a 3/4-wave on 2 meters do the same thing? Also, out of curiosity, would this thing work on 440 mHz? I don't have EZNEC, so I can't graph this out.

Thanks for any help on this.

A simple resonant antenna such as a 1/2-wave dipole has a purely resistive feedpoint anywhere along its length it may be cut into. So the feedpoint can be adjusted to match a feedline Zo between 73 and several thousand ohms.

But unless the antenna is fed at its centre, both wires of the line whiz up and down with the high RF antenna volts and the feedline radiates. This may or may not be desirable. After all, there's no power wasted.

The same applies to an elevated vertical which, with its radials, is resonant. Its feedpoint is resistive anywhere along its length and can be adjusted to match any feedline Zo from 37 ohms upwards. The problem is how to stop current flowing along the outside the coax. Coax chokes can help.

Source record: 155481

anyone out there have the specs on the hft1500 tuner? i am feeding a 80 meter wire in the center with 450 ohm ladderline and converting to a 4-1 balun once inside the house. on 160 meters a inline wattmeter shows a 2.9-1 vswr on 160 meters, however running anything close to 500 watts thru the hft1500 causes arcing.

You can feed a longer than 1/4 wl antenna with a simple series cap and
do the same thing. This is how I feed 3/8 wl inv L's. Where you feed
it is not really going to change current distribution if thats the
plan. Only lengthening the antenna will do that. Where you feed it
doesn't matter as far as the current. Only the feed impedance.

This has already been tried. The common thought in the past was that
ground losses were lower than a single monopole, but this was found
not to be true. So yes, you can change the feed impedance, but that
won't lessen ground losses. You will still need the same amount of
radials for a certain level of ground performance. The gap ad
jibber-jabber will say increasing the feed point level will reduce
ground losses, but I don't buy it. The best way to get a decent small
high efficiency vertical is to use very low loss hiQ coils, and as
much capacitive loading as possible,"IE: wires" etc, and have as many
radials as possible. MK

The beam will work ok. At least good enough to tell when the band is
open. You can still hear other sigs even if not pointed at them most
of the time. Also the beam may hear DX on 6m that the verticals won't.
I use a 3 el yagi here on 6m, and use nothing else. For ssb/cw
anyway..Lately, if 6m is open, it's sporadic E skip most of the time.
Doesn't take much antenna to hear or work E skip. It's obvious when
the band is open. Will be many sigs usually. MK

Thanks John!

I have about 60 ft of wire up 25ft in a L shape fasion. I have a 8' ground rod outside the shack I have a piece of #14 about 65 ft that runs along the house foundation. Also connected to the ground rod is a 10ft piece of #10 going to the shack. I have the tuner inside the house mounted to the wall in the basement. Should I move it out side? I'm not sure if it would work in the winter. It gets pretty cold up here in GreenBay,WI The manula says that it should not be used if it is colder than 15 -F I would have to say it stays -10 - 20 -F During that season. I'll try and take some pictures and post to my web site so you can see how it is set up.

Alot depends on the matching device used by the antenna. You can
always check the swr and see if it is low. If so then you can try
transmitting on it and see what hapens.

Bob, you are absolutly correct. I revisited the MFJ website and found
everything you posted. Yesterday when I was checking to see what I
might be able to do about my problem all I found was the non-free
telephone numbers. Why? I haven't a clue. Naturally, calling them
on their nickel is the answer. Thanks so much.

Gentleman, might anyone have a manual for a Hygain DX-88 antenna? I purchased this antenna for a dear friend for Xmas and the operator I purchased it from had no manual. Any suggestions would be helpful. I have contacted Hygain but they are not planning to have manuals in PDF format out for some time yet. 73... KB0OYD, the Old Yeller Dog :-)

Stray shunt capacitance at the output of a random wire tuner can lead to excessive losses. These tuners are not designed for low impedance coax loads. Beside you might get a high current point and ruin an already marginal tuner. Its everyone's mission in designing efficient antenna systems to reduce stray C. If you want to play with coax loads get a tuner that will handle those loads. Huge currents can flow. The Icom manual is specific of antenna lengths etc, they say this for a good reason.

If you going to modify this tuner, you might as well just get a high efficiency low loss roller inductor tuner, that will cope with coax.

Years ago I was living in a second floor apartment of an old Colonial here in NH. Had direct access to the walk in attic, so initially I decided to install an in-the-attic 15 meter dipole. Could not get that thing to load or tune for the life of me. Gave up and eventually installed some outside dipoles and a vertical. It wasn't until my landlord decided to put on a new roof that I discovered the cause of my problem. Under a couple of layers of asphalt shingles was a metal roof! Kinda hard to tune an antenna in a tin can!!

Glad your dipole is working out for you. Have fun and good luck!

Jack

How about 'Contact', starring Jodi Foster? IIRC her dad is a ham, and she winds up working as a radio astronomer.

It may not count as ham radio, but in Anaconda, the guy tries to call for help on a CB radio right before he gets eaten by the giant snake. Too bad he wasn't a ham!

1246. Vertical Antenna Question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-30 04:37:59 UTC
From: theplanters95@aol.comnospam
Message-ID: <20011029233759.17131.00000531@mb-fh.aol.com>
Source record: 155498

I have decided to put up a modified ST. Louis Vertical (without the coil) which would be about 20' for the vertical and 20' for a radial feed with ladder-line. I live in an antenna restricted area, and am thinking of a good low profile antenna. Already got a deal on a 20' fishing pole to use as a mast. When I want to operate, extend the pole, and when done collapse the pole.

Would it be better to use a short run of coax (less then 20' either rg58 or rg59)? Primary bands will be 20-6. I have also thought of making tv-twinlead verticals for this bands and feeding it with coax. The main problem I have is no way to have a decent ground or radial system (maybe 2 random length, plus a very short chain link fence).

Which feed system will be better? Which would be better at reducing RFI?

Please respond directly to theplanters95ataol.com by replacing the at with @.

THanks,

Randy KA4NMA

I've heard there's a late '30s/early '40s movie titled something like
"Here is Your Hobby: Ham Radio" or "This is Your Hobby: Ham Radio" or
somesuch. Supposedly it's been on TCM. There's also an Andy Rooney
movie where he's a ham (the second Boy's Town movie?), and one of the
Nancy Drew movies has Nancy's boy friend hamming it up with a full
rack (of radio equipment...) Not to mention that Bonita Granville was
a cutie...

1250. CHECK CNN : A USN SUB IS DOWN !!!

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-30 05:39:08 UTC
From: cathexis@your.haterols.com
Message-ID: <3bde39f9.630618596@news.erols.com>
Source record: 155502

Turn off the radios and tune in CNN:

They are reporting that a USN Sub, the "Cuttlefish" has gone
down off the No. Calif. Coast.

Apparently, the boat rammed another (russkie) sub. NOTE:
US Hams are ON THE SCENE !

That's right, currently most communication channels to the
sub are in-op. Comms are being handled by "Hambo", a
trained California Sea Otter belonging to Norcal - the No.
Ca. Amateur Radio Club. CNN reports Hambo has the
ability to relay simple Morse code messages from surface
to sub by tapping mussel shells on the steel hull of the sub.
Hambo is able to reverse the comms by slapping his flippers
in the cold, pacific waters off no. cal. once on the surface.
where members of the Norcal club are standing by.
This is an incredible Ham story -- Check it out !!!

Source record: 155509

Wow...

This is NOT a simple question.I guess this is not the answer
You want, but I CAN'T withstand the temptation to answer
it literally!!

So You want to build a transmatch for a balanced line, "any"
length antenna system, very high power. Then we are talking
air-wound baluns, and a whole lot of kilovolts RF. And NO snap,
crackle and pop? Some small corona noise You might have to live
with: You can break the laws of Your state (altough not recommended),
but You can not break the laws of nature..

So, the simple answer is that the antenna tuner You describes does
not exist (or, very rarely) in the "ham" world.

You'll have to build it. Or get it surplus from an old SW BC
station (not a lot of them in the US, bit easier on "our" side of
the atlantic, er??)

To build one, You'll need a variable inductor WITHOUT a swich
or a "roller contact" which gives "snap, cracle and pop".
Such a thingamajig is called a variometer and does actually
exist, see
http://www.wireless.org.uk/vario.htm
This design is for European LW ham band, so don't count on that it
will be a good one for Your needs. But the principle is there.

Then You'll need some REAL huge voltage variable caps to be sure
of no "snap crackle and pop" there. Perhaps You can find them at
an old MW broadcast site? Leidner elaments are a nice amateur
attempt, but they are ultra-lossy (guaranteeed no snap, cracle
or pop, but I GUESS You'd want Your RF power "in the Air", not
to make warm salt water..Hi). If no old capacitors show up You
can make them Yourself. Not very easy, but possible. A lot of
TIME needed. If You have got lots of $$, you can have them made.
Another tough question is the air-wound balun. In the old days
Johnsson&Johnsson used to make pre-made air wound coils (small
insulating spreaders inside), VERY NICE THINGS, would be
interested myself if I saw them at a hamfest... An old amateur
might have them for You.

If You ar beginning to concider a small compromise, plastic core
can be used. DO NOT USE UNTREATED PVC: IT IS LOSSY (=snap,crackle
and pop will show up) At
http://privat.schlund.de/s/skluge/coilbld.htm

You can find a description of how to make PVC a much more "better"
coil former.

Assembled, we have the "perfect" matchbox. The "" shows that it
will not tune very short antennas (e.g. a 2 feet antenna on 75m).
To do this also, You need extra inductance en masse. Take 2 plastic
dustbins (PE, polyethene is GOOD!) and cover them (to a certain
degree dependent of diameter and Transmatch data) with Litz wire
- un-evenly wound! The distance between the turns should be "greater"
at the warm end, all to avoid snap, crackle or pop due to voltage
breakdown between turns). These dustbin coils will make a nice
accessory to Your Transmatch.

Now You can make almost anything!!! But how will Kellog's react when
Snap, Crackle and Pop are not there any longer??

73's de SM6HCJ

>Rick WA1RKT

I have an elevated 4 square array on 40 meters. I could have elevated
the 80 meter 4 square array as well; I didn't.

My personal experience with lightning strikes just about exactly fits
the Polyphaser nomograam for hits over time vs. height. That is if you
adjust it for the fact that Central Texas here is worse than average for
such things and places like some parts of Florida are even worse yet!

Even the 9 feet up or so that is minimal for doing this on 40 meters and
producing the minimalized number of radials effectiveness you seek is
bad news during lighting strikes. That 9 feet up, at the frequencies of
interest during a strike, when taken together with the tens of thousands
of amps in current, produces a HECK of a step voltage up there at the
base of that vertical, Sir.

Bringing the feed line off to romp into your lovely shack at minimum
cost is a super fine way to invite Dr. Zeus to romp into your lovly
shack in a super fine way as well. Like those advertisements on TV
about how well you'll be pleased with those men's suits, "I guarantee
it!" As far as I have learned, the only way to get the protection
needed is to come straight down to the ground and go through the normal
process of -- you guessed it -- ground rods with -- you guessed it --
radials down on the ground! You then bury the line going back to the
shack and all is well.

But like the old cultural comment, "He who washes after touching a dead
body and touches it again, what has He gained from his washing?"

You've still got the time and money invested down on the ground even for
the minimalistic sink system for the lightning mitigation. And it's

really a fair start at .. radials! Right there down on the ground.

Now all this works reasonably well for ONE vertical with NO 'moving parts' upstairs! But it isn't worth a flip in the land of Dr. Zeus for low band phased arrays, to my bitter experience. I have a nice little pile of burned up phase boxes which are framed in my junk collection. It's kinda like competing for attention from your date when you take her to see Elvis, if you know what I might mean! (Mike, PLEASE take me to see Elvis, oh PLEASE take me to see Elvis!) Yeah, such a hound we have for you, indeed! ;)

Yes, Dr. Zeus does tend to compete for your attention and that of all metalica around 'im! Chuckle!

And, in truth, there is really 'safety in numbers' here, grin! If this whole affair is down under the protective shadow of a much larger tower array which will take the hits, that's a different story too! So said, if you opt to let this live in the shadow of a very famous front man, do take care to think which direction you don't want the vertical to play well in. The segment toward the dircction of that much taller tower will be noticably less effective in your contact play because of the shielding effect of that tower's presence. Many people putting up verticals in proximity to taller towers do not realize or think about that. You have to get a fair number of wavelengths away from a taller tower to avoid this.

And when you do, back comes Dr. Zeus! He also can create a pretty fair step spike run-up in nearby metal thingee's many wavelengths away during hits ... even to trees and other living or non-living things! That's due to the rolling ripple-like wavefronts that spread outward away from the main strike point. They too can do wonderful neat things to your nice elevated vertical game if you don't bring it all down to the ground and sink things there.

(Mike! Take me to see Elvis again, please?) ;) "No."

Let's just summarize it by saying that nine feet up is a real hill for a stepper! Your 30 feet up will be much more of the same, if you are in a part of the country that has this problem, I think.

Faced with the experience of paying several times over the years for all the mess, come time to re-work the 80 meter array, it stayed down on the ground. Now, with it, and the decent sink zone that ground mounted radials create which are a part of it, comes ancillary peace of mind with the elevated array for 40! Since that all went in, *IT* takes the hits, and I've stopped buying replacement parts for the phase box on the 40 meter array! But I don't lose 80 meter stuff and it stays out of the shack as well.. Has for years now! (At least via the antenna farm! Not necessarily in the reverse from hits on the power line! That'a a whole 'nuther issue!)

Elvis still exists on tapes, CD-ROM's, VCR's - HBO .. I;m sure you understand ... ;)

Sincerely ..

--> Sleep well; OS2's still awake! ;)

This is a fairly common problem on 160, especially with a 4-1 balun on
the output.

Probably because your antenna actually has a very low impedance on
160 meters. This can cause high voltages internally, e.g., T networks.
You might encounter this problem unless your antenna is up around 40
meters.

> Which feed system will be better?

You have a number of problems. If you go with ladder-line, you will
need baluns at both ends. If you go with coax, you need to use low
loss coax like LM400. 20ft is a terrible length for a 6m vertical
as most of the radiation is at a high take off angle. Limit the
height to about 12ft if you want reasonable 6m performance.

Your 20ft idea would make a reasonable antenna for 20m-10m if you
use an autotuner like the SGC-230 at the base.

> > 73 ken w8ob

This is not rocket science. What is the length of your ladder-line?
The feedpoint impedance is about 10-j1000 ohms. The SWR on the
ladder-line is over 100:1. Your 4:1 balun was designed to work
into 200 ohms. What impedance is it seeing? The voltage necessary
to force any power at all into the impedance the tuner is seeing
will cause arcing in most tuners. You need some matching at the
antenna to make it work on 160m.

Reg, Roy

What exactly are you buys saying/asking here?

The mathematical formula...

Zo = sqrt((R + jwL)/(G + jwC))

Assumes that a transmission line can be mathematically modeled by it's RLCG primary parameters as incremental series R, series L, shunt G, shunt C, per unit length. [This is a "low pass line".]

[We all know that many simplifying assumptions are made with this particular formula... e.g. "lossless"--- If R and G are small enough to be negligible when compared to jwL and jwC then Zo = sqrt(L/C). Is this true even at DC!

Zo = sqrt((R + jwL)/(G + jwC)), is a good first order approximation, but as we all know, these primary RLCG parameters are not really constants.

The largest first order deviation being the skin effect on R, etc... A "more accurate" mathematical model would include other "perhaps parasitic" elements as well.

For example, what about series C which comes into play if the line is not perfectly straight, what about R and G when the two conductors are not made of the same material, etc....

I have often wondered what an accurate formula for Zo of a long line with one conductor of silver and the other of rusty iron looks like.

An interesting side question, what does the the equation for Zo of a high pass line... i.e. one with DC blocking where the line is modeled as series C, shunt L... etc... look like?

Are these the kinds of questions you guys were trying to raise with your questions, or was it something else?

Best,

>
> Does that sound right to you?

According to all I've read, if you have the antenna at a 1/2 wl up
with 4 radials, it will be appx equal to a ground mount with 120
radials. At 1/4 wl up you will need appx 8-10 radials for the same. At
1/8 wl up, you will need about 60 to do the same.
>
> Do any of you have personal experience with elevated vs. ground
> mounted verticals?

Sure. I ran a 40m 1/4 vertical both ground mount and elevated. The
ground mount I had I ran up to 24 radials. "I planted these in
stages". The antenna was ok, but no real barn burner, and was lucky to
equal my 36 ft high dipole on medium paths. I then planted the antenna
on a 36 ft rat shack pushup mast with 4 sloping radials. The
difference was quite large. The elevated antenna ate the ground mount
for lunch. Of course, I didn't have the proper number of radials for
the ground mount, but that was part of the problem. I didn't have the
room to lay them all out in the yard. The elevated GP beat the dipole
quite handily on medium to long paths. To VK at night the GP would be
an average of 4 S units better than the dipole on the average radios S
meter. I would see the same receiving. I'm totally sold on elevated
verticals. Another plus is the ground/space wave from the elevated GP
is much stronger around the area than the ground mounts. I used to
talk to people way out IH-10 80-90 miles away with ground wave
signals. I was strong everywhere in town, even if the band was dead.
I ran that antenna along with a KW plus on 40m at late night. Few in
the USA could keep up with me unless they had arrays of some type. I
used to be 20 over 9 in Tokyo. Most all average people I worked on 40m
at night said I was the loudest thing on the band. Only the guys
running phased arrays, beams, bobtail curtains could beat me. It was
well worth the hassle. With my antenna it also doubled as a 5/8 GP on
17m. I used a 24v relay to bypass the coil.
>
> I have a Butternut HF-2V that I was planning to ground-mount for 80/75
> and 40, but it would be easier to elevate it 30 feet or so and run at
> least four 1/4-wave radials on each band ... as long as performance is
> likely to be comparable.

I'd go for it. But I'd also pay attention to Mikes lightning warnings. Myself, I never took a strike on mine, and mine was about 68 ft up at the tip. 36+32ft.
But I used the metal mast as a direct path to ground and was well grounded at the base. I really don't think I would have had a problem if hit because I kept all lines going down the mast to ground. Never let the coax hang in midair to the shack. ALWAYS route it all the way to ground at the mast, and then route it along the ground to the shack. I did take two strikes on this mast later after I took the GP down, and had no problems whatsoever. The lightning hit the mast tip and went to ground. It ignored my dipoles etc which were mounted just under that tip on the mast. So if it had hit the GP, I imagine the same would have happened. It would have gone on straight down to ground. I always ground all my coaxes outside during storms because I don't use suppressors. Beware that to equal the performance of 4 radials on 40m at a certain height, on 80m you will need double. 8 radials for the same performance. MK

Jack, I didn't read every posting in this thread thoroughly, so maybe this has been covered already, but I think it's not too hard to make sense out of all of this. My impression is that the biggest discrepancy you see can be resolved by back-calculating the dielectric constant from your capacitance measurement. With polyethylene dielectric, I would not expect the capacitance to have much dependence on frequency, at least in the kHz to several MHz range. If you use the dimensions and the measured capacitance per foot to find the relative dielectric constant of the dielectric, then plug that back in, what do you get for Z0? I'll let you go through the calcs...do you get something close to what you measure then? If you do a careful visual inspection of the dielectric, do you see anything interesting?

Surely there are second-order effects, but things like the change in inductance with frequency (over typical ham HF freqs at least) is pretty minor; and even the reactance added by the copper loss isn't very great in medium-size line at 2MHz and above. (More interesting to describe that in terms of loss per unit length, I think.) But nailing down the dielectric constant to put into the formula isn't trivial...at least, I don't think it's a good idea to assume the value from the description of the material.

Cheers,
Tom

Tom:

The spec on the cable is 30.8 pF/ft and I measured 30.9 pF/ft at 1000 Hz. If you use the standard formula for capacitance of coaxial cylinder, with air dielectric, you get 14.53 pF/ft using the published dimensions (confirmed by actual measurement with micrometer). Based on measured C, I calcalate Er for the poly as 2.12, which is 10 percent below the published values for poly (2.25 to 2.30 depending on your reference).

If you use this calculated value of Er = 2.12 and the dimensions of the cable, you get Zo = 47.9 ohms. Not quite 50 ohms, but closer than the value of 45.99 ohms you get if you use the published Er = 2.3 value.

I also made reasonably careful measurements on Vf using a 1/4 wave open section, signal generator, frequency counter and spectrum analyzer. Vf at 7.097 MHz = 0.658. This calculates out to Er = 2.309,

so I think the "real" Er is around 2.30, just as the published Er for poly states.

I bought an indoor "rabbit ears with amplifier" several years ago. We live in a remote, rural location and our only other option is satellite, and I don't watch enough TV to justify satellite expense.

Yes, in our situation it works, ours has a switch to turn the amplifier off and on. When the switch is off, most of the reception is terrible. When it is on there is a significant improvement.

Now, I know I would get a much better picture, etc. with a good outdoor, roof-top antenna, but I did not want the hassle of installing it. Now, would an indoor amplified rabbit ear set-up work for you??

I don't know, I recommended it to my father-in-law and he saw no improvement in his signal, probably relates to the factors noted by other posters.

I bought mine from C.Crane and Co. They have a website www.ccrane.com. They no longer stock the model that I bought, but they do stock another model. I would not buy the cheap looking models I see in the local discount store, but Crane is pretty good to work with.

You might consider double-checking to see if the amplified antenna from Crane is -- or any other place you buy it -- returnable....If it is, try it and if it does not work, send it back.

True, it doesn't change the ground losses. What is does is increase
the radiation resistance, so the efficiency goes up. The ground
losses and the radiation resistance add to become the feedpoint
resistance. Increase the radiation resistance and the efficiency goes
up.

I didn't say an elevated vertical, I said an elevated feed vertical antenna. They are not the same thing. An elevated feed vertical antenna is mounted on the ground (and connected to ground) and the feedpoint is higher up on the element.

This is a way to get a perfect match without adding any reactive components.

By the way, I tried it with AO last night, and it can give you a perfect 50 ohm match. Don't remember the exact numbers (am at work---AO is at home), but it was something like 36 ft tall (on 40 mtr) and feed point at about 30% up from the ground.

What I am interested in is if it would work with a folded monopole.

I am in the process of putting in radials. Have ten in the ground now. And hope to have 20 in before winter sets in. Will drive my ground rod this weekend. I have read in some old QST articles that the ground can be improved by adding rock salt or copper sulfate in a pit around the ground rod. Does this improve the ground for purposes of radiating? I know it won't improve the ground for purposes of a nice lawn. Also is this practice legal anymore with EPA restrictions and all? Also wondering if the ice removal product Potassium cloride(?) would work. Thanks.

Source record: 155430

"Old QST articles" were written under the influence of pre-HF technology during which era hams were using frequencies below the AM BC band. Low frequencies tend to penetrate the earth several feet and such soil conductivity enhancements will prove beneficial, however on the HF bands, penetration is only a few inches and the best solution is more radials.

Now for lightning protection, this is a different matter and those chemicals might help.

I'm considering a new vertical for 80 meters. HF2V is the best candidate right now, but someone can try to talk me into something else. Please, do...
There is a top load kit available for the Butternut. Their web page says little about it. How much improvement in bandwidth would I see if I use this, and secondly, would it improve signal strength for dx??

1279. vertical dipoles

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-31 01:19:27 UTC
From: WB3BBC <wb3bbc@arrl.net>
Message-ID: <9rnjnm$7t8$1@bob.news.rcn.net>
Source record: 155432

Cebik's papers have gotten me interested in experimenting with some vertical dipoles. Most literature on this subject advises running the feed line away from the feedpoint for as long a horizontal stretch as possible. My interest is in "collinear" dipoles, coax fed, where the coax runs through the center of one element. Initially, I plan to pull the outer braid of a piece of coax back over the outer insulation for a distance of 16 feet or so, hoist the end of the center conductor as high as possible, and see what happens on 20 meters. I expect to be able to get the lowest part of the antenna about 30 feet above ground.

How is feedpoint impedance affected by this method, as opposed to running the feedline away at 90 degrees?
What other differences between these feed methods should I be aware of? If it goes well, I may construct the same
antenna from aluminum tubing and add a current balun to the feedpoint. Finally, perhaps shorten the elements and add a large "hat" to each end. Would this be considered a Marconi?

Thanks in advance for any suggestions...

That's not surprising, but it doesn't necessarily mean anything.
If you turn off an amplifier, it probably has about 15 dB loss instead
of 15 dB or so gain.

The real test would be to compare it to plain rabbit ears without
an amplifier.

I have borrowed and scanned the supporting documents for the government propagation prediction software "Transmission loss Predictions for Tropospheric Communication Circuits", volume one and two. These documents have all the equations required for doing what you are trying to do. That's the good stuff. The bad stuff is that I scan at a decent resolution which means these documents are quite large (29 MB and 35 MB) and can't be emailed. I would be glad to upload them to an FTP server if you have access to one.

Also, software, example programs, docs, and source code (in FORTRAN and C woohoo!)
exist at http://elbert.its.bldrdoc.gov/itm.html . I believe that a lot of commercial software that does these calcs is base on this stuff.

Let me know about the scans I have.

Source record: 155436

I coiled up coax in several diameters and numbers of turns, then measured the impedance with an HP vector impedance meter. In most cases, the impedance at resonance was around 2k ohms, plenty for good balun operation. The resonance is quite broad, resulting in a very good balun for about three bands. The best combinations of coax length and number of turns, based on these measurements, can be found in the ARRL Handbook.

Danny:
There are numerous duplexers available from equipment and antenna manufacturers. My experience with a couple of them is that they are high pass/low pass with a crossover around 200-300 MHz. So, wide band coverage is still there, just split between the two connectors, below 250, say, comes out the 2M connection, and above out the other.

Hi Jim,

Sorry, but this is wrong. The radiation resistance is more a function
of the physical volume of the antenna than the feed point
characterisitics of that same antenna . The feed point Z is tailored
by transformer action and is thus related to the actual radiation
resistance through the step-up you are pinning your hopes to.

The radiation resistance is aided by the action of the thick radiator
somewhat, but nowhere near aiding your efficiency arguement. It is
still roughly the same 30-odd Ohms in relation to the same lossy
ground elements. The radiation resistance AND the loss are still on
the same side of the transformer. It is the combination of THESE two
values added that are being stepped up - no efficiency boon in that.

1287. Antenna Installation? - SF Bay Area

Newsgroup: rec.radio.amateur.antenna
Date: 2001-10-31 07:08:39 UTC
From: Richard Friedman <rchrd@rchrd.com>
Message-ID: <3BDFA376.81B07F6F@rchrd.com>
Source record: 155440

I want to put up a Cushcraft MA5B 3 element beam antenna but
I can't do it myself. I'm past the age where I can climb up on
the roof or similar gymnastics. So I've been looking for an
outfit that installs antennas professionally. I've asked at
the local Ham Radio Outlet and a local TV shop without success.

Any suggestions? I need someone who knows what they're doing
and can tell my what my options are (roof, side of the house,
give up), and do the job. I'm not constructing a tower.
I don't have enough room for that. Probably something off
the back porch against the house that clears the roof and
gets the beam high enough without alarming the neighbors.

I also want someone who can do this safely and cleanly,
without jamming a foot thru a window or dropping the
antenna into the backyard. I know what would happen if
I tried to do this myself.

Does anyone do this kind of work anymore? The TV store
said that now that almost everyone has cable they rarely
put a crew together to put up an antenna, and the last
time they did a ham antenna was a number of years ago.

Any leads or suggestions greatly appreciated.

That's what it is in my area. Brings up a tale relating to that 7KV.

About 20 years ago I installed a C-band sattelite TV receiver system for a friend who lived out of town on a 7KV rural line. His house was surrounded by trees and we had to site the antenna about 200 feet from it to get a view of the Clark belt, and at that, one young tree about 75 feet from the dish still was interfering with the easternmost satellite. I suggested that he might want to cut that tree if he wanted to receive that satellite.

Some weeks later he got around to sawing down the tree, and as it fell the top of it barely brushed the 7KV highline.That contact caused a huge spark, he said, and after that his satellite system wouldn't work, so he called me to check it. The entire satellite receiver system along with his TV set looked like it had undergone a lightning strike with much smoke and blackened, exploded components. The voltage pulse caused by the falling tree brushing against the 7KV highline induced a high voltage spike through the earth into the cabling between the satellite dish and his house that had a strikingly similiar effect as a lightning strike. All the electronics had to be replaced.

What adding salt is likely to do for you is help dissolve your new radials in a much shorter period of time than they would have ordinarily. Unless your radials aren't working for you, I'ld suggest just leaving them as they are, either bare or covered. You'll note that you don't read many recent articles suggesting the addition of salt to improve ground radial efficiency.

==========

At HF, current penetratrates into the earth more than just a few
inches. It is a maximum on the surface and decreases exponentially
with depth. "Skin depth" is the depth at which current has fallen
to 37% of that at the surface,

Below about 10 MHz skin depth in soil is roughly -

1.5 * Sqrt(R / F) feet,

where R is soil resistivity in ohm.metres (= 1/conductivity) and
F is MHz.

So with an average sort of resistivity of 150 ohm.metres
conductivity = 0.0067), at a frequency of 1.9 MHz, skin depth is
about 13 feet.

At 10 MHz it is about 6 feet and appreciable current flows at twice
that depth.

At 30 MHz soil permittivity is important and in an average soil
skin depth is about 8 feet.

There's a program SOILSKIN which displays a table of skin depth
versus frequency for given soil resistivity and permittivity.
Download in a few seconds and run immediately.

A better way of doing what you want is to place a good rf choke on the
feedline 16 feet +- from the feed point , rather than expose the coax sheild
to the elements. also this allows for you to seal the feedpoint for weather
proofing a good choke can be made by coiling the coax in about a 6" coil ,
there was a chart printed somewhere with the number of turns needed for each
band but I can't remember where I saw that at the moment.
The feed point impedence should be close to 70 ohms on such an arrangement
and would match 50 cable without much trouble.

good luck,

I suggest you look into a short "tip over" type tower/mast set up. That way
you can install the beam while standing on the ground, then raise it up. The
"rasing" gear can be a hand cranked winch or an electric winch. Examples can
be seen in Ham Radio Outlet and Amatuer Equipment Supply catalogs.

You might contact someone who installs Satellite dishes. Most of those folks know what they are doing. Call a local radio/TV station, ask for the chief engineer, see who climbs their towers etc. Surely the is a ham radio club in your area, I know here we have some really good people and have an idea about antenna installations.

WB3BBC wrote:
"I plan to pull the outer braid of a piece of coax back over the outer insulation for a distance of 16 feet or so, hoist the end of the center conductor as high as possible, and see what happens on 20 meters."

It should work just fine if the weather is fair when WB3BBC does that. See Terman`s 1955 "Electronic and Radio Engineering" page 902 Fig. 23-34 (c), "flagpole antennas".

The makeshift version constructed all from the coax itself may not be the best decoupled from the feedline version to be built, but it works. I`ve done it.

Coax antennas have often been maligned. My experience does not confirm the poor results some claim. I`ve installed coax antennas on portables and mobiles, esecially boats. There are no radial eye pokers. The results were good every time.

Hello people,

In reality the objective of my thesis was to design a multi-band PATCH!! antenna for mobile communication that could transmit and receive for 4
or 5 frequency bands for mobile phones (including the GSM and UMTS bands). Reading all the stuff from IEEE of Carles Puente and much more thesis and information, when I discovered that the structure of such kind of antenna could changed easily for specific frequency requirements because of the self-similar structure that enhances multiband behavior the Sierpinski gasket patch antenna started to interest me.

But continuing analyzing this antenna I got a lot of problems which till now aren't solved:

1) Till now I couldn't make simulations that were in agreement whith those published by Carles Puente using the software of HP Momentum which is ADS. The first problem was that because of the complexity of the structure it was very hard to implement that. The problem would lie in the fact that the edges of the triangles which connect the subgaskets weren't connected to each other and therefor the current couldn't flow from the bottom to the top of the gasket. Till now this problem isn't resolved!!!Must there be a path of finite width lying over the edges for the current could radiate in all gaskets??

2) Because of the complexity I was unable to design such an antenna for the requirements because of point 1. Therefor my tutor said to investigate only a two or three-iteration Sierpinski gasket but because of the same problems what to do with the edges the simulations were not in agreement with Carles Puente.

3) Therefore I searched more information for analyzing these type of antennas and searched for other software packages. It seemed that IE3D, Ensemble,FEKO and NEC were investigated already with that kind of antennas.

4) The problem is that all the articles that I have are only based on experiments and the FDTD method. Is that the best method??Why not choosing MoM??Is the structure really so complex that such formulas not exist while for a triangular patch they are known??Can the formulas for the triangular patch be changed when cutting a hole (one-iteration Sierpinski gasket) so that these frequencies can be calculated??

5) Because till now I was very disappointed about my results (I don't have nothing yet) my tutor asked to choose maybe for another solution to write a program in Fortran based on the EFIE method that can be applied to arbitrarily shapes. Is that the convient way for my thesis. Because of the complexity of the problem he lower the weigth of the proyect to only include three bands instead of five. The 1800 GSM band and the two UTMS bands. All these bands seem to lie a factor of 1,09 from each other.

Therefore I ask you if it is really useful to continue with such a complex object (a Sierpinski path) antenna to include these three bands or to make use of more simpler antenna.

Do you know of a configuration of patch antennas that can include these three bands??

Thanks all the people for supporting me because I am really anxious because of the complexity of the problem and the fact that I started this thesis last year in november having no good result.

Although RF currents decrease exponentially with increasing depth, it may be of interest the loss in the ground can be calculated by assuming the current is uniformly distributed across a slab of soil having a thickness equal to the skin depth with nothing underneath.

The same applies to the resistance of a round copper wire. At frequencies where skin depth is much less than wire diameter the RF resistance is equal to the DC resistance of a copper tube with a wall thickness equal to skin depth.

It so happens the skin impedance Zs of copper is not purely resistive. Zs has an angle of exactly +45 degrees, ie., it has a reactance equal to its resistance. The reactance is in fact inductive reactance.

Now skin resistance and reactance together increase as the squareroot of frequency. It follws that the skin inductance DECREASES with the squareroot of frequency. It is of course internal to the conductor.

In the case of a transmission line the internal skin inductance must be added to the external inductance which is a function of the line geometry. When the total inductance is L the line impedance Zo = Sqrt(L/C).

C is not affected by skin depth and is constant. And so Zo of all transmission lines slowly decreases with frequency as skin gets thinner.

So should a line manufacturer state the frequency at which Zo = 52 ohms applies ?

Which has taken us a long way from the ritual of peeing on the ground rod every morning before breakfast.

Regards, Reg, G4FGQ

Richard Clark wrote:
"It is still roughly the same 30-odd Ohms in relation to the same lossy ground elements."

Andrew Corporation will sell you an almost indestructable stainless VHF ground plane antenna. It`s main advantage is that it is a folded monopole and shorts out most the energy in a lightning hit.

Another advantage is that although its radials are horizontal, it is adjusted before shipment to present an almost perfect match to 50-ohm coax at your specified frequency. You tell them what connector you want on the antenna.

Adjustment is accomplished by lengthening or shortening the slide trombone vertical radiator, then clamping it tightly.

The good match to the 50-ohm coax minimizes transmission line loss.

First and foremost, their is nothing distinctive about a "PATCH"
antenna except in its application (flat, circuit board construction
style). It is made this way because the scale of the wavelength
allows it, not because the electromagnetics demands it.

If you want to saddle yourself with an application specific
constraint, that is commendable as academia so rarely considers the
reality of engineering. However, academia has its focus on the
transfer of knowledge and clearly you are suffering from peripheral
details impeding this. Your tutor is not doing his job (fire the
bozo).

It's about time that you take a cue from the lack of support and
detail offered from these "scientific" reporters. This is simply very
poor science indeed and appears to be commercial covers and puff
pieces suited to impressing investors; or in creating a cult.

You have yet to mention EZNEC which can handle this design work in a
heart-beat. Is your school too miserly to provide the money to cover
this very affordable package? I imagine they spent far more for far
less.

This conforms to the old saying "a poor carpenter blames his tools."
Stop worrying about differences and simple start doing tests. The
resolution to your problem is not to be found in the answer to your
question above.

Fire that bozo of a tutor - this guy is absolutely clueless (he IS
that poor carpenter).

AND as I asked before, enumerate each and every frequency. Stating a
"factor" suggests to me that you are struggling with non-essential
data. In other words your questions are unnecessarily obscured by
this jargon and tedious specification.

Hi Rafael ,

You haven't shown any progress in the last month as you appear to be stuck on very trivial details and going in circles.

I asked you last time about this "factor" you speak of, and you did not respond. So to reveal how much work you pile on us when you ask for help (it serves us both when you provide details, not your written assignment), I will wing it - if I interpret it wrong that is YOUR problem (do you really need more?).

Each resonance lies in factor of 1,09 from the next? So, that means I could presume the first is at 1.00 GHz, the second at 1.09 GHz, the third at 1.19 GHz, the fourth at 1.30 GHz, the fifth at 1.41 GHz? Or are the five frequencies separated by 1.09 GHz? It would be infinitely simpler if you simply state what frequencies - n'est pas?

But the cold hard truth of it is it does not matter because you are not going to compress 5 resonances into such a small bandwidth. You might get two - if you try really hard and only for the first and fifth.

You really need to brush up on the first principles of design. That is, you should have long ago resolved how practical and real this thesis was. That effort should have taken no longer than a week to conclude that it is impossible for five bands. Impossible that is unless you start to focus on the goal (5 bands) rather than the method (sierpinski).

That is, you have violated first principles in trying to force an artificial solution. Wishing that the sierpinski will work will not make it happen no matter what tool you use or how many programs you write. Leave the wishing to Puente, your tutor, and the cult of fractals and train to become a scientist and engineer instead.

Richard Clark wrote:
"Sorry, but this is wrong. The radiation resistance is more a function of the physical volume of the antenna than the feed point characteristics of that same antenna."

Then why the posting?

See page 890 in Terman`s 1955 "Electronics and Radio Engineering". "This is the resistance (Radiation Resistance) that, when inserted in series with the antenna, will consume the same amount of power as is actually radiated.----Unless specifically stated to the contrary, it is customarry to refer the radiation resistance to a current maximum in the case of an ungrounded antenna, and to the current at the base of the antenna when the antenna is grounded.

A 1/4-wave shunt-fed grounded vertical obviously does not exhibit the radiation resistance at its feed point. Maximum current coincides with the base of the tower and so does the radiation resistance. The object of shunt-feeding the vertical was likely to get the impedance up from its low radiation resistance value. Richard Clark is right about that.

Best regards, Richard Harrison, KB5WZI

>antenna about 30 feet above ground.
>.....

Stripping the insulation and "pulling the outer braid back"
over 16 feet of coax is not as simple as you might think. It's
much less trouble to make a sleeve monopole (similar to what
you're describing) by connecting 16 feet of #14 wire to the
coax center conductor, and sliding a 16 foot section of
tubing (1/2" copper plumbing water pipe) over the coax,
leaving the insulation on and soldering it to the end of
the coax (shield). You only solder the tubing end to the
coax shield at the end where you soldered the #14 wire.
Optionally you could slide 16 feet of ground braid over
the coax insulation and solder similarly only at the
upper end. In either case you have a type of balun and
antenna structure that has been successfully tried and
tested many times. Do a search on "sleeve monopole"
some time.

I hope this helps and that your antenna is a
success, no matter how it turns out as a radiator ! !
(No need to ask how many non-radiating, but educational
antennas I've made !!!)

Peter Brackett wrote:
"Assumes that a transmission line can be mathematically modeled by its RLCG primary parameters as incremental R, series L, shunt G, shunt C, per unit length. (This is a "low pass line".)

At radio frequencies, the ratios R/omegaL and G/omegaC are so small that Zo can be taken as a pure resistance equal to the square root of L/C ohms.

Then, there is the special case for all frequencies where the line is made to have R/L=G/C to produce the so-called "distortionless line", where attenuation does not increase with frequency, but has the same attenuation for all frequencies. See Terman`s 1943 "Radio Engineers` Handbook", page 173.

Some "low pass line".

Best regards, Richard Harrison, KB5WZI

If I understand correctly, Rafael is interested in modeling a patch antenna. Although it's possible to make one with an air dielectric, patch antennas almost always employ a substrate with high dielectric constant (e.g. alumina, with k = 10). None of the NEC family of programs, including EZNEC, has provision for including the dielectric, so can't produce even approximate results. This isn't necessarily a shortcoming of MoM, but of its common implementations.

Rafael might be interested in U.S. patent number 6,127,977, "Microstrip patch antenna with fractal structure" (Nathan Cohen). It looks to me (a non-lawyer) like the first claim covers virtually all fractal antennas placed on a substrate:

1. A microstrip patch antenna including:

a substrate having spaced-apart first and second surfaces, said substrate having a thickness substantially smaller than a wavelength at a frequency to be coupled to said antenna;

a conductive pattern defining a fractal of iteration order N disposed on the first surface, wherein said fractal is defined as a superposition over at least N=1 interations of a motiff, an
iteration being placement of said motif upon a base figure through at least one positioning selected from a group consisting of (i) rotation, (ii) stretching, and (iii) translation;

wherein said motif is selected from a group consisting of (i) Koch, (ii) Minkowski, (iii) Cantor, (iv) torn square, (v) Mandelbrot, (vi) Caley tree, (vii) monkey's swing, (viii) Sierpinski
gasket, and (ix) Julia; and

a conductive pattern disposed on the second surface.

1. Increase the length of your wire to about 76 feet. If going inverted L--try to get the vertical portion as high as you can.

2. Put at least one radial about 76 feet plus 10% directly under your elevated wire.

3. Put several other radials at least .2 wavelengths long on either side of the one in #2 above.

4. Seal up the control cable and coax connections on the coupler well--and point them down if you can. Protect it from direct sun and large hail.

The directions for the AH-4 coupler indicate how to attach the coax to the coupler. If you bought yours new, you must install the PL-259 connectors on the supplied coax or coax of your choice. Put your coax through the wx boot first!

DO NOT USE COAX ON THE OUTPUT SIDE OF YOUR COUPLER--REGARDLESS OF WHAT OTHERS MAY HAVE TOLD YOU! The coupler is for end feed and balanced feed only.

You may attach the coupler to a loop antenna by attaching one end of the loop to the output lug side of the coupler and the other end to the ground lug. Depending on where you place the coupler in the loop will determine direction of gain and polarization of your signal, as well as nulls.

You can attach 450 ohm ladder line to the coupler in the same fashion--just split it enough so you can hook one wire to each lug. Hook the other end to a dipole cut for the lowest frequency you intend to operate on. 100 feet of ladder line seems to work well on all bands with a dipole from 88 to 130 feet.

You do not need radials with the loop or ladder line feed.

The coupler is NOT designed for use with a coax fed dipole. Do so at your own risk.

The AH-4 coupler is NOT designed to work on 160 meters. Do so at your own risk!

The AH-4 coupler is NOT designed to work below 7MHz with an 8 foot whip. It will work great on 80 with a Hustler mast and 80 meter coil, or an 80 meter Hamstick type antenna, but not so well on the higher bands with these antennas--replace them with a plain steel whip for 7MHz and up.

You can make extension cables for the AH4 coupler. I have run couplers 200 feet plus distant from my rig. Use good quality coax, such as 9913F and decent size 4 conductor wire for the control cable to combat feed line loss and supply voltage drop.

DO NOT USE COAX ON THE OUTPUT SIDE OF THE COUPLER. Coax should only run between the rig and coupler. YOUR ANTENNA STARTS AT THE COUPLER OUTPUT.

Roy- to my reading- this is the MAJOR shortcoming to his (Nathans) patent- the use of a substrate is not only a part of the major claim- it actually has to use both sides of the substrate. In other words, if you use only one side- you are not within his claim. The phrase:
> >and
> > a conductive pattern disposed on the second surface.
> >
looks like a late addition by his Lawyer. THat word "and" is defining the limits of the claim.

This is probably a provision put in as a way to avoid someone elses patents, that only used one side. without this feature, he probably would have not gotten a patent.
I could be wrong, but I have seen this as the hidden flaw in his claims, and easy to avoid.
We will not know, really, until the claim is tested in court.

Too bad this does not help Raphael.

How about another radial question....

How important is the wire diameter on the effectiveness of radials, particularly below 7 Mhz?

If I were to lay a bed of radials, say 12 radials, would #14 wire be significantly better than #22? I gather that adding additional radials will make more difference....but "does size(wire diameter) count"?

Thanks

The end that has the longest spacing probably goes toward the
transmitting station. What you really want to look at is to see which
is the longest element and which is the shortest. The shortest will go
toward the transmitter.
It should make a big differance on which end goes toward the
transmitter. YOu might not be able to tell it by ear if the station is
strong due to the capture and limit effect of a FM signal. It could help
eliminate some multipath distortion where the same transmitted signal
arives at several differant times due to receiving a direct signal and
some reflected signals.

Examples where the subject formula might be considered incomplete:

1) Increase the applied power - keep going - more...
2) Increase frequency - keep going - more - way more...
3) There are probably other cases as well.

Obviously formula (in general) have limits beyond which they break down and are no longer applicable (or it becomes obvious that they are incomplete). This isn't an issue so long as nobody tries to deny it. It is almost pedantic. Apologies for mentioning it.

for durability and current handling. I'd recommend using at least
as large a wire as the center conductor of your coax, and bigger if
you have it handy or want more durability. But hey, if you have a
lot of small guage looking for a purpose, try it out.

Kind of interesting that no hams in the area have offered to help. Why not get in touch with one or more of the clubs up there and see if a couple of hams will offer to help.

Sorry I'm not in the bay area, I would be happy to give you a hand.

Good luck
Dennis - W6NYC

I have a 1/4 wave 40 meter vertical up 10 feet with 2 radials. My
10-40 meter G5RV is in
a inverted vee configuration up 30 feet. On 40 meters the vertical
outperforms it
by at least 3 S units. According to what I have read a vertical up 10
feet or more
only needs 4 radials to do the same job as the many needed on the
ground. I'm
going to add a couple more radials when I get a chance.

Source record: 155381

"Roy Lewallen"
> Rafael might be interested in U.S. patent
> number 6,127,977, "Microstrip patch
> antenna with fractal structure"

Perhaps Raf would be interested in following up on the academic opportunities inherent in another world-class Fractal Antenna patent by the same inventor, US Patent Number 6,140,975. In this patent, The Inventor briefly mentions a second-iteration Minkowski fractal antenna and tosses in (almost casually) an increased gain fudge factor of +2.709 dB.

Maximum Gain per ELNEC: "2.091 dBi"
Maximum Gain per The Inventor: "4.8 dB" (also isotropic reference)

Each such antenna would therefore seem likely to have a gain (averaged over the sphere !!!) that exceeds unity !! If the experimenter can provide the feed point of such an antenna with a decent mismatch (like a simple open circuit for example), then such an antenna could potentially emit more energy than it intercepts.

My concept would be to take one of these new-technology miracles, installed with its phase center at the exact center of an extremely strong (reflective) metal sphere. The antenna would be connected to a carefully-matched loading resistor through a simple (but highly reliable) switch. At the appropriate moment: open the switch, random thermal motion bumps an electron, RF waves are emitted, then reflected between the antenna and the sphere, and start building up....after a few million amplitude doublings - BANG !

This arrangement would form a new weapon of unprecedented power - the Second-Order Minkowski Experimental Fractal Antenna Bomb Levels Everything.

The inevitable military acronym is, of course, SOME FABLE...

1329. Coil loading versus linear loading

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-01 02:07:28 UTC
From: fantbb@yahoo.com
Message-ID: <c2a65514.0110311807.2edeac61@posting.google.com>
Source record: 155382

I modeled a short 35 foot 80 meter vertical up 10 feet on EZNEC using linear loading and then again using a loading coil. I was surprised to find that the impedence for linear loading was around 8 ohms and around 16 ohms using the loading coil. The coil was set for 1 ohm of loss and about 820 of inductance. When I calculated the efficiency of the two it came out to be around 57 percent for the linear loading and around 70 percent using the loading coil. Using 5 ohms for ground loss and 1 ohm for wire loss. The patterns were almost the same. Anyone have any ideas on why there would be this much of a difference? Linear loading made the antenna much more broad banded also.

In my experience, the term "all pass filter" refers to a filter having a flat frequency response but a time delay that varies with frequency. This inevitably produces distortion (of a type often called dispersion). Although a distortionless line is technically an all pass filter, it's a trivial one.

I'm using 60 feet of 26AWG enamal wire. It's endfed from my apartment window via a MFJ tuner, and held up on the other end with 25 pound monofilament fishing line. I've even used larger buttons (clothing type) for the insulators. It's up about 20 feet. Maxi-Sealth!! Run up to 100 watts into it and can work to any US border from Minnesota. Cheap and it does work.

Boy, you guys really missed the actual question I asked, which was: Is Johnson producing unglazed 6" line spreaders, or are they counterfeit?

BTW, I ran some water submersion tests on the spreaders, and they are certainly hygroscopic, and therefore worthless for outdoor use.

Thanks for all these suggestions and the personal emails
I've gotten so far.

I guess my biggest surprise was when I called HRO to find out
if they had someone to recommend for installing antennas and drew
a complete blank.

I am going to first contact a couple of local ham clubs. I've not
joined any of the local groups due to lack of time (why do some meet
at 9am on Saturday mornings??)

What I need is a starting strategy (will it be on the roof or
with mast by the side of the house -- tilt-over or mini-tower..etc),
and then probably have one of the TV antenna installers do the
heavy lifting. But first I need the advice from some of the
old-timers about the right way to mount an antenna, and from a local
contractor about the right way to attach it to the house without
doing terrible damage.

I guess I'm surprised that no one seems to do this kind of work
anymore. But the suggestion about the satellite dish installers
is something to look into.

Thanks all!
I'll report back once I get the antenna up, but its looking like
that might be months away. Meanwhile the MA5B, deconstructed,
sits neatly on the porch, glaring at me..

I can`t tell from Johnson`s webpages. The New E.F. Johnson is a Nebraska company and seems concentrated on APCOA and trying to pry away some of Motorola`s business. That is a formidable task for anything other than Maverick and token purchases.

Johnson`s information pages are mostly "under construction" except for complete radio sets and services.

My impression is that they`ve decided to buy rather than build components.

The new E.F. Johnson indicates it will respond to questions. A web search on E.F. Johnson immediately produced their site.

Hi,

Enamel wire is cheap and easy to find. The only problem with it is
that it can kink fairly easily. That tends to weaken it. In some cases
black insulated stranded wire will hold up better. It's a little
larger in diameter which makes it a little bit easier to see. To
counter that you can play with various colors to find one that blends
in best. Some people have gone with a gray to blend in better.

Enjoy!

Pascal---your best bet is to do a "Deja" search of the newsgroups as there has been MANY discussion threads concerning this antenna. New folks who ask this question always get one of two answers:

(1) it's a "dummy load" hung up in the air and is worthless or,

(2) It's a useful antenna as long as you understand its limitations. It will NOT perform as well as a dipole antenna cut for whatever frequency you want to use and yes, and it is no where as near efficient as other configurations that many folks will recommend to you when they see your question.

Having said all that, it is useful because it obviously has a wide frequency operating range. Works very well from 80-10m, but not very well on 160 and the SWR goes up to about 3:1 on that band. For operators who need to work outside the normal ham bands and/or need the ability to quickly move between frequencies without retuning the B&W is a good choice. I use one both for ham and military operations and am pleased with it; your experience may vary. Many U.S. military and governmental agencies use this antenna all over the world. As you probably know it is also quite expensive compared to a simple wire antenna you could use with a tuner.

All depends on what you need it to do and if you're to make the conscious decision to accept the "cost of doing business" in decreased efficiency then you may want to consider it.

Good luck....hopefully this will prevent the inevitable "flame wars" that flare up every time this subject comes up.

Hi,

I now have an ICOM 706. I also have an infant. I only get to use my rig at 10:00 PM or after. I often spend 20 minutes or longer unwinding antenna feedline and then setting up antennas.

I was looking to make a more permanant installation, however I am in an apartment. I have a question..

1. My radio is near a window. It one of the vertical window types so it is tough to feed RG58. It is also tough to conceal. I thought about using transparent 300 ohm antenna feedline available at Radio Shack. In this way I could feed it through the window, run it around the outside ot the building, a 20 foot run. I need a matching network before getting to the antenna - what should I consider?

Pascal
The answer provided below is a very good one. I have the B&W-1.8-30 antenna hung from two trees and suspended about 20-25ft above the ground. In this location it works as a NVIA antenna system and provides me with coverage over a wide area (Indiana).
A good friend of mine told me that on some bands the antenna is only 12% as efficient as a dipole for the same frequency. He indicated that this is about 1 S-unit loss.
What ever the answer you get from others, I am very happy with my antenna and recumbent it to anyone who wants wide frequency coverage at minimal cost. The advantage of changing frequency/band without using an antenna tuner is worth any minor loss of radiated power. Having said that remember that a cut/tuned dipole/beam will provide maximum signal transmission/reception. The B&W can not provide that. It has other purposes.
Good luck.

> radials as possible. MK

As I stated previously, yes, ground losses don't change, but what
happens to the 'radiation resistance'?

According to Kraus's Antennas, the signal radiated is proportional to

sqrt(P/(R11+RL))

where R11 is the 'self resistance' and RL is the resistive loss, and P
is the power applied to the antenna. But what is the self resistance?
In the case of a single wire quarter wave monopole it is
approximately 36 ohms, the resistive part of the complex impedance.
My question now is, with a folded monopole, does RL (which includes
the ground losses) also get 'transformed'? The power P is being
applied to the 'transformed' (4x) impedance in series with the loss,
not directly to the radiation resistance. (By the way, Kraus has a
different derivation of the 4:1 ratio besides the 'transformer ratio'
method.) I did not see (or could not find) in Antennas where he
mentions the radiation resistance of a folded monopole.

The only way to reduce the ground loss is to reduce the groundloss.
However, if the radiation resistance of the antenna is increased,
keeping the ground loss constant, the efficiency will go up.

As someone else mentioned, I like to have my antennas DC grounded for
lightening protection, which a single wire monopole is not (unless you
stick in a lossy choke or something).

As I recall my history, QST was not around at that time. QST started
after hams where using HF. Read the book '200 meters and down'. 200
meters is 1500 kHz, at the top end of the BCB. Since we are talking
wavelength, 'down' refers to 160, 80, 40, etc.

Besides, even though sparc was broadband, I don't recall reading
anything about hams using anything below 535 KHz.

I do remember reading the recommendation about the salt. It was
sometime after WWII.

Hi,

I have a bunch of snap-on RF chokes from Radio shack and some RG-8X coax. Are theses snap-on chokes suitable for using at the antenna feedpoint as an effective RF Choke (on 10 meters)? If so, how many would I need to chain onto the coax?? Any reason not to do this?

Thanks,

Scott McClements.

Here's an alternate idea I got out of Dave Ingram's Wire Antenna book:

Use RG8X for the feedline/center conductor. Cut off the end flat, at the other end put on your 259 connector.

Now take a spare piece of RG8, for 20 meters use the 16 feet or so you describe. Peel off the outer black layer (exacto knife worked very well for this, just a little time consuming). Now pull out the center conductor and insulator out of the outer braid, so you leave the braid hollow.

Now feed the RG8X through the center of the RG8 braid (takes patience, but it's not hard). Pull it back a little far, then peel back a couple of inches of the RG8X braid, and solder the two together.

Now attach some 14 gauge (or so) wire to the center conductor in the correct length. I also put in a simple RF Choke by making five turns of the RG8X into a six inch loop just below where the lower part of the RG8 braid is when the antenna is vertical.

I then took it outside, and adjusted the length of the center wire and moved the lower part of the braid up and down until the antenna analyzer was giving me loving messages. (Use a small piece of electrical tape to hold down the lower end of the RG8 braid).

I then took it back inside, and wrapped the entire length of the braid in electrical tape, to keep it safe and free from snagging on things (which reminds me, I gotta buy more electrical tape).

Hope this helps, 73's,

Jeff, Roy:

Heh, heh... SOME FABLE... as many have noted here, for several reasons, the USPTO patent examination process has declined markedly over the past 20 years. I think the rapid decline started in the early 80's with the first assaults on the PTO's budget.

Today that patent examination process is just a shadow of it's former self and it seems that almost *any* claims can be "got past" the examiners with enough *persistence*.

The PTO's patent examination staff has become completely overloaded with the increased workload and smaller staff, and so disheartened by loss of the *best* staff due to retirements, and other attrition. All of this, coupled with the inability of the PTO to recruit new examination staff in the "go go high tech" era of the past decade seems to have resulted in an unwritten attitude towards claims examination that could be summarized as, "just let it pass and the claims will be settled in litigation later... if anyone cares". For those reasons as well... the number of court contested patents and court overturned patents has soared during the same period!

I'll bet today one could even get the previously perennially rejected *perpetual motion machine* through the patent examination process today!

On a brighter note... I just read where the USPTO is going to hire 500 new patent examiners this year. And I believe that they expect a healthy budget increase. In today's job market they should find lots more applicants. I just hope that they get good examiners...

Thoughts, comments...

Crazy George wrote:
"Porcelain insulators no. Steatite a different mix."

My search`s first response: Steatite, gray-green or brown mineral that, in granular or crystaline form, is the most abundant and massive variety of the mineral (talc), French chalk, a granular soft white variety or steatite used by tailors for drawing lines on cloth. Steatite is also known as soapstone.

The above definition comes from Microsoft`s Encarta Online Encyclopedia.

The next entry comes from Maryland Ceramics & Steatite Company, Inc.. Their table shows their steatite insulator material "impervious to water absorption", having a dielectric strength of 225 volts per mil, having a dielectric constant of 5.9 at 1 megacycle per sec., and having a (relatively low) loss factor of 0.021 at 1 megacycle per second. Steatite is relatively strong mechanically.

The clear 300 ohm cable from Radio Shack has such thin wire, it's rated only for indoor use. An alternative might be TV coax -- it's 75 ohms, but that might be close enough, and it's available in a white jacket.

>Roy Lewallen, W7EL

Hi Roy,

Your comments on the dielectric constant are an interesting problem. However this should not restrict Rafael's apparent need to model.

This again returns to first principles. Investigate the fundamental relationships and THEN add the complexities that so confound the issue. It is the height of foolishness to try to do everything from the ground up together (inventing a new math package to support this complexity much less investigating its application). This form of blazing trails is best left to professionals - academia simply does not have the motivation nor the intellectual bandwidth to perform this.

This presumes something will be DONE and not just analyzed to paralysis. It begs the question: just how necessary is it for any software package to have this detail of coping with a heavy linear loading of dielectric. Does it contribute 100% variation to the answers found without it, or just 3%? If this is not investigated in advance of progress, progress is not going to occur. It should only take two physical models built, one in air, one on the substrate to determine this variation from a real and applied point of view. If such a determination is taxing, I see no merit in the continuation of modeling in software.

Once that variation is determined, the next question is: can it be extrapolated so that special program enhancements are not necessary to the normal survey of designs in a first round elimination?

However, if we look at the complaint:
>>The problem would
>>lie in the fact that the edges of the triangles which connect the
>>subgaskets weren't connected to each other and therefor the current
>>couldn't flow from the bottom to the top of the gasket.
It contains nothing of modeling problems identified being uniquely dielectric in origin. In fact it reveals a particular narcissism within the fractal community of eschewing all comparisons in search for the holy grail. That is, the focus on one particular form, the Sierpinski (which I had modeled years before - this is NOT particularly unique after all) to the exclusion of others (and for no apparent reason other than someone else did it in a non-verifyable manner - who would've guessed?). No, the so-called scientists in this field practice a shabby form of intellectual (ineffectual) browsing.

However, to return to first principles. There is a problem, but does its solution bear on the completion of a successful analysis? That it so stalls Rafael and his tutor (sic) that they focus on this to the exclusion of the sierpinski only adds to the mystery and awe of the "claims" made. Cheap thrills indeed.

I've played with enough of these forms to know that sierpinski, koch, and the rest offer trade-offs that could progress this without the need for modeling in software. First principles would ask: do you have the appropriate form? How does it compare to others? AND then you stick in on that patch. Having done so, do the same comparisons hold across the forms on the patch now? In other words, does the k of the patch come into the problem at all? Does it present a solution, or another problem?

I will put it bluntly for all to understand: does the k of the substrate contribute to the compression of resonances to fit into this band of frequencies?

This, as I've described above can be tested with only two models (which I presume is the point of this all - making a real working antenna). This seems to be last in the agenda - it should be first. It should have been done to even determine if the thesis had a valid presumption.

If it is determined that this k and the substrate do compress the resonances: by how much? Is it sufficient? If not, this needs to be reproduced with another form (koch triadic or quadratic perhaps?). Such questions in research are often laid out in a table for risk assessment which allows the researcher to map out a campaign of study and analysis rather than just groping in the dark (the fractal scientific community apparently has yet to discover fire).

Every one of my questions shows the painfully unprepared state of Rafael's search and his tutor's incompetence. This focus on the nature of the incapacity of software modelers is a chimera of delay and capitulation to ghosts in the closet.

And to point him at fraudtenna as a source of information is a cruel trick. That patent is wholly useless for any scientific inquiry and only serves to propagate the legend and myths. Given your experience in even mentioning the topic with threats of suit in response; Rafael deserves to be warned that there is every possibility he will be harassed if he follows up on that lead. I would wish that it were otherwise, but I have yet to observe ANY correspondent come out of that process without being mauled. Well, perhaps there are several one-time posters from AOL accounts notably close to the servers that shared our good doktor's line of postings. That too, increases the prospects of bogus science strutting the stage like a painted whore.

I use #22 radio shack 300 ohm antenna feed line to my wire antennas. I have been using it for years, and in many different qth. The clear stuff may degrade faster in the sunlight. That means changing that 10 foot peice every few years...

I am a big fan of the Johnson Matchbox. Get them on ebay (pretty ones $100, Ugly ones $50.) I use it on 80 to 10 including all bands in between. The advantage is that since the tuner is balanced, you don't get rf back down the feed line. This year at field day we ran 3 dipoles from 3 matchboxes and it was not until we were packing up to go home we realized we had never established a ground for anything! You MAY get rfi in your system because you are so close to your own antenna, that can happen with any antenna.

I run my home antenna as a "random length loop". it is over 200 feet long. If you can sneak a set of wires up under the eves where the christmas lights should go, (put it up at the same time!) you should be able to get yourself a respectable antenna.

Good Luck.

Since I was taking a break from my code developement, and still had Microsoft developer studio open, I wrote a quick C++ WINAPI application to check this out. It said that 24 kv in and 240 v out is a ratio of 100 to 1. ;-)

By the way, my HP calculator agrees. So does a manual calculation using paper and pencil (you do remember how to do that, don't you?).

Another by the way...In my parents neighborhood I believe the distribution is 3300 volts (suburban). Don't know what it is at the home qth (quasi rural).

I took my bride to the public library yesterday and while she was locating her book I wandered over to the periodicals.

I spied CQ Magazine, which I do not subscribe to, and leafed through it.

The lead article by my friend, Donny, W7DD, was one that had me checking the cover to make sure I hadn't picked up the April issue. But that's another story.

The next item of interest was an antenna article. It was titled, if I remember correctly, "The Clothesline Antenna." This was an 'adjustable' folded dipole. I didn't take time to read all of the claims to fame but I distinctly remember that according to the author, a folded dipole has both a lower angle of radiation and is quieter than a regular dipole. I didn't know this before.

You really can learn something new every day.

> this, and secondly, would it improve signal strength for dx??

That is probably for 160 m use. Unless they have a way of reducing
coil turns on 80m when using the hat. I'm not sure about bandwidth,
but adding the top loading wires is a much prefered way of loading
than using an inductor. For 160m use, the top loading would be the way
to go. I think the HF2V can also work 30m with a kit, but I
forgot..Nothing wrong with the HF2V. It's as good as any for a 80/40
antenna that is not a tower. Better than most trap verticals by a
quite a bit. The only other one I can think of offhand that might be
better for 80m is the hi-tower, and I'm not sure they even make that
anymore. Lots more work than the butternut also as it's a tower with
stingers. If only used on 80m, I'd build one myself out of scrap
antenna tubing or a tree hung wire and save big $$$$$. An inverted L
might work just as well or better. I hardly ever buy prebuilt
antennas. My A4S beam is the only one. And I got it free...:) MK

1363. Re: Elevated Feed Vertical Antenna

Newsgroup: rec.radio.amateur.antenna

Source record: 155269

Yes, the loss also gets transformed. If you want to use that equation, R11 (Rr) and Rl must be referenced to the same point. When you do this, you find that both are transformed by the same amount. You're welcome to use 36 ohms as the "radiation resistance" of a folded monopole, or you can use 4 times this amount, as long as you specify what you mean by "radiation resistance". But if you want to use the formula, you have to multiply the ground system resistance by 4 if you use 4 X 36 ohms for Rr. You see, loss resistance isn't an absolute value any more than radiation resistance is -- its value depends on where it's measured and how it's defined. It's this fact that slips by in simplified analyses.

Radiation resistance is an ambiguous term, sometimes meaning the feedpoint resistance and sometimes the resistance at a current loop. When using the former definition, you can change the "radiation resistance" simply by moving the feedpoint. Yet you're not changing the efficiency by doing so. When you calculate the loss resistance looking into the antenna at the new feedpoint, you'll see that it has the same relationship to the radiation resistance as before. That is, by moving the feedpoint you're changing both the loss and radiation resistance seen at the feedpoint.

If you look at the currents in a folded monopole, you'll find that each conductor of the monopole carries 1/2 the current of the equivalent unfolded monopole. This amount (1/2 the unfolded amount) enters the ground system via the transmission line shield connection, and an additional 1/2 the unfolded amount enters the ground system via the connection of the second folded monopole conductor to ground. These currents are in phase. The result is that exactly the same amount of current enters the ground system when an element is folded as when it isn't. Consequently, the I^2*R ground loss is exactly the same. If you ignore conductor loss (a reasonable approximation), you'll see that the same fraction of the applied power is lost in both antennas, so the efficiency is the same. Since I is half as large and effective conductor R twice as large in a folded antenna than in an unfolded one, the conductor I^2*R loss is half as great in the folded antenna. But this is virtually never a significant difference in full sized antennas.

It's a common misconception that folding an element reduces ground loss, and one that's often used to help sell antennas. But a misconception it is.

You are too modest. There are certainly some patents which are very valuable. As I am sure yours are.

However... of the 6,000,000 plus US Patents, only a very small percentage have ever "turned a profit".

In my experience in industry, I have found the greatest value of a patent portfolio the defensive use in negotiating cross-licensing agreements with other "players" in the industry. These cross-licensing agreements border closely on violating "anti-trust" law. These cross-licensing agreements are usually of the form, "I won't sue you or charge you for using my patents if you don't sue me and let me use yours for free." These patent cross-licensing agreements between the "800 pound gorillas" in an industry are useful ways of preserving duopolies and cartels to the disadvantage of small and emerging players who have few if any patents in their portfolio to trade.

In this role the uniqueness of patents, although always important, is apparently not of as much value as the sheer quantity of patents that you have in your portfolio.

Reminds me of a Harry Turtledove "alternate history" novel featuring Samuel Clemens as a reporter in San Francisco. He loathed the mayor, and had named his dog after him. After a particularly frustrating encounter with said mayor, he returned and apologized to the dog, saying "When I named you after the mayor, I thought I was insulting him. It turned out, though, that I was insulting you."

Can anyone explain how the stick on fractal antennas they sell on TV for cell phones work? Common sense tells me that if I place an antenna under a battery, the proximity would at best detune it, and at worse make it totally useless. What is it that I am missing?

I am so glad that you brought this up, Wes.

Now, I can understand why the plain old wire dipoles that I use today are
not as quiet and do not work DX as well as those folded dipoles I used in
1946.

Gotta run out and find some of that good brown polyethylene twinlead . . .

BTW, wasn't that clothesline antenna published in QST a year or so ago? You
crank it in or out to move the feedpoint for various off-center-fed
thingies (technical term).

1377. Your opinion on this antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-02 01:06:35 UTC
From: vtail@hotmail.com
Message-ID: <3be1f04a.308286244@news.netis.com>
Source record: 155290

I am considering putting up an antenna for all band use.

What I am considering is a dipole for 80 meters and an inverted vee for 160, both connecting to the same center point (becoming a two-in-one composite antenna), fed with open wire feeders, and tuned with a Nye Viking MB-II for use on all bands 160-10.

The dipole will be up about 50 feet, meaning the apex of the inverted vee will also be up about 50 feet. The ends of the inverted vee will be up about 10 feet.

A dipole, by itself, will give me more gain broadside, and the inverted vee will give me a more omnidirectional pattern at the expense of some gain. So, I'm hoping with this hybrid to get some of the benefits of each.

Am I likely to gain any advantage over the simple 160-meter inverted vee by itself?

Thanks...

Hello--

I was sitting at my desk one day, and what sounded like a shotgun fired
across the road startled me. Simultaneously, my PC's UPS switched into
backup mode, and my XYL inquired what happened.

After checking the circuit-breaker panel and the feed line to our house,
I called the utility company and they dispatched a repair crew. In the meantime,
I located the binoculars and scanned the nearby pole transfomer, noting that
something limp and fluffy rested on the transformer's top surface.

When the utility repairman showed up, I asked him what had happened.

"A squirrel blew the fuse-- probably when it tried to climb the insulator onto the
hot wire," he replied. "It's odd that this one left a tail-- usually we never find 'em.

Either they either vaporize completely or get blown free."

Think about that before you reach for your chain saw<g>.

If you replace RG8x in good condition with 9914 in good condition, the only difference will be that you'll reduce the transmission line loss. Unless the antenna is perfectly matched, the SWR will always be better with lossier cable (RG8x in this case), but adding loss isn't usually a desirable way to improve SWR. (Although sometimes it is for some users -- that's exactly what the B&W broadband antenna and some other commercial antennas do.)

I, too, am an apartment dweller. I ran about 66 feet of 26 AWG emanal wire to a nearby tree. Using buttons (clothing type) and 25 # monofilament fishline the antenna is SUPER STEALTH!!!. I run some insulated hookup wire (about 18 - 20 AWG) into my MFJ tuner. Oh, be sure to add a 33 foot insulated wire counterpoise from your tuner arount the baseboard of the room. Works great! I can put about 100 watts into it and have made contacts in a lot of states (MN QTH). If you want to compare notes, give me an email, happy to help.

I have 2 UHF (440mhz) and 1 VHF (2m) yagis that I would like to sell (best offcer) or trade (for a dualband 2m/440 vertical). These items must be picked up in the Toms River, NJ area. For complete information, please visit http://vhfradiobuff.tripod.com/forsale.htm.

Source record: 155285

Brad:

Yeah, our next door neighbor had that happen a couple of weeks ago. The local line crew tells me that squirrels cause 90% of their outages and would be 99% if people would keep their trees trimmed. (The other 1% is people whose cars are strangely attracted at high speed to power line poles.) H. L. & P. has a product which purports to solve the problem, some plastic configuration which keeps the squirrel far enough away that it can't touch live and ground at the same time, but with 1 transformer per customer, our utility hasn't seen the economics of that solution yet. Our present service is 7.4KV, and there is usually some evidence found at the bottom of the pole.

I am getting close to ordering one of the Am-Comm automatic screwdriver antenna controllers. The company has been very responsive to my questions, and even sent a copy of the manual by e-mail. I have read everything available on the unit and it sure looks like it will do the job. Just wondering if anyone has tried one yet.

Of course, the lossier the coax, the lower the SWR (when the SWR is not 1:1).
If your SWR goes up when you use less lossy coax, that's a good thing.

There are better solutions for antenna feed point chokes.
The W2DU type balun uses full torroids with specific formulations for this application. You can find sources for these torroids and even purchase a complete unit from advertisers in the back of QST like The Wireman.

I have used a setup like this on 40 and 80 Meters for years. I have a balun in the center and fed with coax. It works great on 40 and 80 and can be used on 15. I have added other elements for 30 and 20 at times, all fed with the same coax. It may be directional but it is hard to tell!

I think it's much older than that. I saw a version in an old QST a while back. Not sure, but I think the QST was from the 50's. I also remember another old article where Don Mix " I think that was his name" used one with a valiant. Also back in the 50's or so. I'd like to find a "tenna-tape" type thing where you have an adjustable center fed dipole. Not sure if they make them any more. Lots of the stuff we use now is just recycled from 50 years ago. :/ MK

I use a Maldol AS-30 Active Hunter. Its a thin metal rod based 14"
(tip-to-tip) whip that screws directly into the stock antenna socket.
Performance seems better than the stock duck on all bands - especially
on 2 and 450. Its super flexible, light weight, is black in color so
matches VX-5R, and doesn't make the radio top heavy - its very light
weight.

If you ground the mast you would likely need to shunt feed it or
something along those lines. If you want to feed a mast with a series
coil, you will want the mast ungrounded. And you usually wouldn't
ground the coil except in a few csses. Some 5/8 wl GP's use grounded
coils as an example,but they are single band with a fixed tap. I'd
rather not ground the coil on a multiband antenna. Can't give you the
rest as I don't know the height of the antenna. And the coil turns
will vary with the diameter which can be anything you want to use. In
general, the bigger the better up to a point. You would want to add
top loading wires for 160 to cut lossy coil turns. You will need quite
a few if you don't use top loading on 160m. This wouldn't hurt for 80m
either. If you made the mast 32 ft tall, you wouldn't need loading for
40m. I can tell you as an example, an old henry amp roller coil I have
that is appx 4 inch or so diameter and 26 turns will tune a 32 ft whip
down to almost exactly 3500 kc when the coil is used at the base. You
will need a lot more for 160m. MK

Hello

I'm thinking of putting up a cheap and small vertical (I'm not allowed to put up large antennas at home due to planning restrictions) and was thinking of the ZX Yagi GP3.

Does anyone in the group have any experience of this antenna? If so, what do you think of it?

Thanks in advance.

I think about 10 turns of the RG-8X with a diameter of 6" right at the antenna feedpoint will be just as effective as a snap-on choke...well it IS a choke.
Does RS tell you what mixture of ferrite is in the choke? You may be putting a mixture on the feedline that won't even attenuate the frequency you're trying to soak up, rendering it almost useless. The RS people won't know what the heck you're talking about.
The best way to get an effective choke is to order it from Amidon where you can select the frequency "to choke".

Body handling: Binary attachment payload not displayed: paul.hurd.vcf

I have been using one for 18 mos with my IC706MK II G switching between my car and RV. It seems to work great. I say seems because I have not tried any other mobile antennas for comparison. I have worked a lot of DX mobile. It will resonate (very low swr) from 40 through 6, without problems. A word of warning, make sure you really ground it well. Not just the antenna mount (I use the Diamond mount recommended by Yeasu) but the trunk or hatchback needs to be positively grounded. You will have tuning issues without a good ground. Just another note, I modified the controller by wiring another switch across theirs to a connector to a remote switch on my dash. The 706 and controller are in the trunk about 13 feet away. This works just fine.

I thought you could hook a coil between the base of the mast and ground. As long as the inductance was correct it would appear as an open to rf but a short for DC.

My mast is adjustable between 55 and 74 feet.. Plan to use it as 1/4 wave on 80, 1/2 wave on 40 (with appropriate matching) and initially base loaded on 160 but eventually I will put top loading wires on it as you suggested. The reason I am shying away from the top wires now is that I am unsure of the interaction between them and 80/40 meter operation. I think it will take a lot of fooling around to get it right where as if I base load it I can use relays to cut the appropriate components in and out for each band. I have 60 133ft radials underneath it. The mast is going up this weekend.

So, Mark, getting back to my inductance to ground...any more thoughts on that?

Thanks and 73's,
Harry

Are you sure we are talking about the same thing Paul? I believe the
Am-Com was only released a month or so ago. You couldn't have had one
18 months ago. And it works on all bands, not just down to 40. Their
web site is http://www.amcominc.com/productdetail.cfm?Prod_ID=957 .
Are you talking about the ATAS-100 controller made by the same
company?

Harry:

If all you want is DC ground, with little effect on the other factors in play at the feed point, then use something like a 2.5 mh RF choke. It will provide the DC path to ground and will have enoough inductance to be a very high impedance to any RF.

Update. The Am-Com screwdriver controller is apparently still in
final testing. Won't be released for another couple of weeks or so.

AMATEUR RADIO NEWSLINE(tm) REPORT #1264 – NOV. 2, 2001

==========

A NOTE TO THOSE WHO ONLY “READ” AMATEUR RADIO NEWSLINE(tm)

For those of you who only know of the Amateur Radio Newsline (tm) as a text newsletter we would like to invite you to listen to the audio version. This Amateur Radio Newsline (tm) script is actually written for the “spoken word.” It is recorded each by professional broadcasters and is available for private listening or rebroadcast over your repeater. Three methods of delivery are available: Streaming audio using RealAudio, FTP RealAudio or dial-in telephone. Please visit our website at http://www.arnewsline.org for a list of telephone numbers (you have to pay your own long distance charges) and links to audio servers providing our voice newscast (for free). We think you will find the time you spend listening to be a rewarding experience.

de
The Amateur Radio Newsline(tm) Production Team

==========

Amateur Radio Newsline report number 1264 with a release date of Friday, November 2nd, 2001 to follow in 5-4-3-2-1.

The following is a Q-S-T.

Hand held radios to Antarctica, Georgia to host the 2002 United States Amateur Radio Direction Finding championship games and the F-C-C takes action on illegal C-B radios. These stories are first on Amateur Radio Newsline report number 1264 coming your way right now.

HAM RADIO TECHNOLOGY: IRLP REACHES ANTARCTICA

Imagine picking up your H-T, calling your friend and asking him how the weather is. He responds with a crisp clear signal and tells you that its 70 below Zero and snowing. Outside your window the thermometer says its 80 and you plan a day at the beach. Welcome to the world of Internet Repeater Linking as the system expands its global coverage to Antarctica. Nate Dueher, WYZ0X, has more from Denver Colorado:

--

The Internet Radio Linking Project has come to Antartica. On October 23rd, Chuck N0NHJ, set up the first Internet radio link on the continent. A few days

later we caught Chuck and a few other hams on the air to ask him a few questions. Let's listen in...

Terry, N0PQV in Denver, Colorado was the first to say hello:

--

[recording]

--

I got a chance to ask a question of Chuck that I wanted to know. Chuck, how many hams are on the station and how many are active on
IRLP?

--
[recording]
--

And yet another question from Ian, M0CJY in Rottherham, Yorkshire, England...

--
[recording]
--

One of the other questions we had was Justin KC0LBH who wanted to know all about that famous Anartic daylight:

--
[recording]
--

That's all we have time for today. If you'd like more information on the IRLP project on the World Wide Web, go to www.irlp.net. This is Nate Duehr, WY0X reporting.

--

Once again, if you are interested in tying your repeater to the Internet Repeater Linking Project go to www.irlp.net on the world wide web. (NY0X, ARNewsline(tm)) {This complete very ecxciting QSO is available in RealAudio at www.arnewsline.org on the FTP transfer page}

**

RADIOSPORTS: ATLANTA TO HOST NEXT US ARDF CHAMPIONSHIP GAMES

The South-East will host the next United States 2002 Amateur Radio Direction Finding competition. Newsline's Joe Moell, K0OV, tells us where and when the event will be held.

--

The Georgia Orienteering Club has been selected to host the second USA Radio-Orienteering Championships, to take place April 19-21, 2002. The competition will get under way near Atlanta on Friday afternoon with a practice

event, followed on Saturday by the main two-meter hunt and on Sunday by the 80-meter hunt.

In addition to the hunts, there will be a cookout on Friday evening, a dinner on Saturday night, and an award ceremony following the 80 meter hunt, all included in the registration fee. Lodging options include cabins in the park and campgrounds with RV hookups. There are also many local motels and bed-and-breakfast inns.

Standard international rules will be used for these foxhunts, which are all on foot in beautiful woods near Callaway Gardens. The Championships are open to anyone, beginner or expert.

Slovakia will host the next World Championships of foxhunting in fall 2002. Positions on USA's team that will travel to these championships will be determined by individual performances in the Atlanta event, as well as in last summer's USA Championships in Albuquerque.

It's not too early to start making plans to attend the second Radio-Orienteering Championships near Atlanta. For more details and registration information, see the official Championships Web site. The exact URL is rather long, but you can get there in just a couple of clicks by going to my foxhunting Web site: www.homingin.com. That's "homingin" -- as one word -- homingin.com. Or you can write to me at my callbook address.

From sunny southern California, where foxhunters are already practicing for the championships, this is Joe Moell K0OV, for the Amateur Radio Newsline.

--

Again, the web address for more information is www.homingin.com. (ARNewsline(tm), K0OV)

**

ENFORCEMENT: FCC VS ILLEGAL CB SETS

The FCC has gone after some illegal gear seemingly designed for operation on the Class D 11 meter Citizens Band. This, as it issues a citation to an alleged supplier of the equipment in Oregon. Amateur Radio Newsline’s Norm Steely, KI7UP has the details.

--

In its September 17th letter to Truck-n-Travel and copied to its owner, Eugene Trucking Haven, FCC Portland Oregon Resident Agent Ben Nugen leaves no doubt as to what is going to happen. Either stop selling non-FCC Certified radio gear or the consequences.

His letter states that last July 23 that agents from the FCC observed uncertified Citizens Band radios displayed and offered for sale inside the Truck-n-Travel located on East Pearl Street in the city of Coberg. The FCC says the radios included four models from Galaxy and one from a company called Delta Force. The Commission says its records show that one of these CB sets

have been granted an FCC equipment authorization. It warns Truck-n-Travel that the marketing of these CB radios, or even just advertising them is a violation of Sections 2.803 and 15.101 of the Commission’s rules. It tells Truck-n-Travel that it can fine them up to $10,000 per violation per day and that can go on to a maximum of $82,500.

The letter then gives Truck-n-Travel the same warning that numerous ham radio violators have received over the past several years. It tells the company that, in accordance with Section 503(b)(5) of the Communications Act, it has 14 days from the date it received the citation to submit any statement it has to make concerning the alleged violation. And the FCC adds that the Commission staff will use all relevant material information it has -- including information disclosed in the Truck-n-Travel reply to determine what, if any, enforcement action is required to assure current and future rules compliance.

--

More on this case as information is made available. (FCC)

**

ENFORCEMENT: NY REPEATER UNDER SCRUTINY

The FCC has told a repeater owner to explain the operation of his machine. A repeater that FCC Special Counsel Riley Hollingsworth says is on the air all by itself:

--

Hollingsworth: “We opened an audit of a repeater opewrating in Elmhurst New York, KB2PRV, after our evidence showed no identification, no appart control operator, and no apparent coordination.”
--

Hollingsworth says that the letter of inquiry went to Ramon D. Florimon who holds the KB2PRV callsign. He was given 30 days from reciept of the October 2nd letter to respond to the FCC. (FCC)

**

BREAK 1

This is ham radio news coming to you from the United States of America. We are the Amateur Radio Newsline, heard on bulletin stations around the world, including the Southern California Amateur Teleprinter Society net serving West Covina California.

(5 sec pause here)

**

RADIO REGULATIONS: FCC CLARIFIES FUTURE OF CORES

The FCC's Wireless Telecommunications Bureau has clarified several issues regarding Amateur Service implementation of the Commission Registration

System--or CORES. The ARRL Letter says that starting December 3, everyone doing business with the FCC--including amateur licensees--must obtain and use a 10-digit FCC Registration Number when filing.

Amateur licensees now registered in the Universal Licensing System or U-L-S already have been cross-registered in CORES and issued a FCC Registration Number by mail. The FCC said it planned another cross-registration by November 28th. Amateurs can check to see if they have an FCC Registration Number via a U-L-S license search. Many Internet call sign servers, including ARRL's, also can provide this information. (ARRL)

**

RESCUE RADIO: JUNGLE RESCUE ASSIST

Ham radio played a role in reuniting with his family a man who had been hiding in the jungles of Guatemala for over three decades. The C-Q Magazine website reports that 72-year-old Salomon Vides of El Salvador emerged from the Guatemalan jungle recently after hiding there for 32 years from a war that lasted about 100 hours.

In 1969, El Salvador invaded Honduras and Vides, a migrant worker, ran into the jungle to escape retaliatory raids. The Organization of American States quickly brought the war to an end, but Vides says he never got the word. He was discovered in August by Rene Sonabo, a taxi driver and Guatemalan ham radio operator, and Sonabo’s son. After persuading Vides that no one was trying to kill him, Sonabo used his amateur station to relay the news to Vides’s stunned family in El Salvador. He has since been reunited with his brother, but the family had not been able to locate his wife and three children. (CQ)

**

THE LAW: THE COST OF ATTACHING TO POLES

The United States Supreme Court is examining a complex Internet case that could eventually affect the availability of online services and what most people pay for them. The court is expected to rule by next summer on a fight over the cost of establishing and maintaining some Internet and wireless networks.

Specifically, the fight concerns the rent that cable television companies must pay utilities to attach wires for high-speed Internet service to the utilities' poles, and whether the Federal Communications Commission can control the rate. The justices also will consider whether cellular telephone companies are entitled to pay government-limited rates for attaching their equipment to utility poles.

A federal appeals panel ruled last year that the FCC does not have the authority to regulate pole rental rates for Internet service. The FCC claims Congress intended it to have that power. The Supreme Court will decide. (Published News Reports)

**

REPEATER OWNERS ATTENTION: RADIO TOWERS FOR SALE

Are you a repeater owner or a club that operates a repeater? Have you ever dreamed of owning your own mountain-top or high rise repeater site? Well if you have, listen up.

In an e-mail to Amateur Radio Newsline, Tom Swierczewski, the Zoning Representative for American Tower Corporation says that the company has several hundred communications towers for sale throughout the United States. According to Swierczewski, sites vary in height from 100 to 400 feet tall and many include large buildings.

If you or anyone you know is interested in this or if you want to receive additional information on specific tower sites, please contact Swierczewski at American Tower Corporation. The information you need to do this is in the printed edition of this weeks Amateur Radio Newsline report. More information is in cyberspace at www.americantower.com.

(Contact information: 1101 Perimeter Drive, Suite 225, Schaumburg, Illinois 60173. His phone number is 847-240-1508 X 663 - Central US time. E-mail is thomas.swierczewski@americantower.com.) (Tom Swierczewski)

**

HAM RADIO BUSINESS: VK MAGAZINE BITES THE DUST

Another failure in the international ham radio marketplace. This, with the announcement that Australia's longest-running electronics magazine has ceased publication.

Victoria’s A-P-C News reports the current issue of Electronics Australia Today will be the last and it’s a decision saddens many V-K amateurs. This is because many generations grew up building equipment from circuits published in the magazine.

Electronics Australia Today traces its history back to Wireless Weekly, which started in 1922. Radio and Hobbies was formed out of Wireless Weekly in 1939. This was renamed Radio Television and Hobbies in the 1950s and Electronics Australia in 1965. (APC News)

**

HAMVENTION 2002 UPDATE: HAMVENTION TO HONOR THOSE WHO PERISHED ON SEPTEMBER 11, 2001

The Dayton Amateur Radio Association will honor the memory of those killed in the September 11th terrorist attacks and the hams who then volunteered their services to the nation by dedicating the 2002 Hamvention to the theme of Emergency Preparedness. In a letter to potential vendors, the Hamvention Planning Committee said that it was very concerned over the terror attacks and believes that emphasizing the emergency communications aspect of ham radio was a very apropos way to honor those lost in the tragedy.

The letter also contained another rather surprising announcement. The Hamvention planners say that they will limit the number of non-ham radio booths normally purchased by those in the computer industry. In fact, the letter makes it clear that the only computer related vendors permitted to the inside

display area will be those whose products directly relate to Amateur Radio.

This will be the 51st annual Hamvention. The venue remains the HARA Arena just North-West of downtown Dayton. The dates are May 17th, 18th and 19th, 2002. More information is on the web at www.hamvention.org (DARA)

**

RADIO MILESTONE: NRCDXAS AT #200

The National Radio Club's D-X Audio Service will have its 200th issue available this month. Founder and producer Fred Vobbe, W8HDU says he does not think that is a bad record for what he describes as a little audio based magazine talking about broadcast radio that was started in April 1985. We say, congratulations to Fred and to the National Radio Club's D-X Audio Service on this milestone. (W8HDU)

**

BREAK 2

**

OUR HERITAGE: HELP RESTORE THE LST-325 RADIO ROOM

Bob Wilder, AF2HD, is part of the team that's restoring the LST-325 Radio Room and he needs your help. Bob says that most of the radio equipment needed for the restoration of the radio room has been found. Also, they have received a donation from a trucking company in the east who is going to pack and ship the stuff on that side of the country and transport it to Mobile Alabama where the work is taking place.

Unfortunately, some of the gear is on the West Coast. It took $190,000 to perform all the work needed to repair the ships hull, front door and ramp, as well as to sandblast and paint the ship. As a result, cash is short.

Bob says that what's needed now is to receive a donation by some west coast trucker or person who can help getting the equipment out there packed and shipped eastward. At least as far as Dallas where the East coasts trucker can move it to Mobile.

Wilder says that Fred Chapman, W4CHT is coordinating the move. If you can help -- or at least direct the group to a trucking company willing to make such a donation, please contact W4CHT by e-mail to nnn0ppe@infi.net . Bob Wilder can be e-mailed at bwild@earthlink.net (AF2HD)

**

HAM RADIO IN SPACE: HAM RADIO BALLOON LAUNCH DECEMBER 1ST

Arizona Near Space Research says that it will launch a ham radio carrying balloon on December 1st, weather permitting. The group had hoped to launch from a local hamfest but the urban location of the event is in enhanced Class B airspace which is currently off limits. Instead, a monitoring station will be at the hamfest event. Full information on the flight can be found on the Superstition Amateur Radio Club website. It's in cyberspace at www.qsl.net/wb7tjd. (Superstition Amateur Radio Club)

**

HAM RADIO IN SPACE: LOTS OF HAMS TALKING TO THE ISS

And while on the subject of Amateur Radio in space, hams world-wide are excited about being able to talk to the International Space Station fairly often these days. This is because Commander Frank Culbertson tries to get on the air for general Q-S-O's whenever he can. And he recently had one with Berto Willems, ON1CAU, who had his tape recorder rolling. Take a listen.

--
Audio Only - No Text Available (Download Newscast Real Audio File at www.arnewsline.org)

--

ON1CAU says that contact took place at about 15:25 UTC during the recent Scouts Jamboree on the Air. And obviously signals were 5 9 full quieting – both ways. (ON1CAU, AMSAT BBS)

**

SPACE EXPLORATION: 2001 A MARS ODYSSEY - A SUCCESS

NASA's 2001 Mars Odyssey spacecraft was safely inserted into orbit around the red planet on October 25 th. This, slighly over two years after the space agency suffered back-to-back failures by Mars missions.

Odyssey arrived nearly directly on its target - 480 miles above Mars' surface. No orbital insertion or areobraking problems were reported by ground controllers. 2001 - A Mars Odyssey is the space probe that hams had been invited to track when it was launched earlier this year. (NASA)

**

INTERNATIONAL: NZART STRAIGHT KEY NIGHT

The first ever Straight Key Night in Kiwi-Land is slated to be held on the evening of Sunday November 4th. Operation will be limited to 80 Meters from 8pm until 11pm local New Zealand time.

The event is sponsored by the New Zealand's Amateur Radio Transmitters which says to lubricate that old Morse key and enjoy an evening of old time radio fun. NZART it will be an activity night in which everyone can be a winner with a certificate to prove it. For more information visit www.nzart.org.nz on the world wide web. (NZART)

**

DX

In D-X, Gary Halstead, K8KFJ in West Virginia reports a top notch trans-Atlantic QSO on 6 meters. On October 23rd at about 13:50 U-T-C Gary contacted CN8LI in gridsquare IM64. The Q-S-O took place on 50.130 MHz with K8KFJ running 100 watts to a M2 loop at only 20 feet. Gary lives in grid EM98 in the Charleston West Va. area. (VHF Reflector)

Also, Reid Hill, KC5YKX of Corpus Christi Texas says by way of the VHF Reflector that he will be doing VHF - UHF Century Club QSL card checking at the South Texas Amateur Radio Club annual Hamfest on November 10th. Reid also says that Mark Mireles, AD5CA will be doing the Worked All States checking at the same event. The Hamfest will be held at Swanter Park in Corpus Christi. Festivities start at 8:00 AM and go to at least after lunch. Contact Reid by e-mail to kc5ykx@swbell.ne if you need card checking but can not attend this event. (VHF Reflector)

**

THAT FINAL ITEM: NEW LOOK TO THE G4NJH PAGES

And finally, a regular voice heard here on the Amateur Radio Newsline is that of Jeramy Boot, G4NJH, in Nottingham England. And over the past several years Jeramy has become known the world over as the Internet voice of the Radio Society of Great Britain’s’ weekly GB2RS newscast. But you may not know that Jeramy is also a webmaster in his own right. In fact he hosts a very popular U-K cyberspace address. We invited him to tell you a bit about its past and where it is today:

--
Audio Only - No Text Available (Download Newscast Real Audio File at www.arnewsline.org)
--

Obviously the next question is where to find the G4NJH web pages. They are actually located at www.innotts.co.uk/~asperges. But don’t worry if you did not have the time to copy it. Just go to the links page at www.arnewsline.org and click on G4NJH. (G4NJH)

**

NEWSCAST CLOSE

With thanks to Alan Labs, Amateur News Weekly, AMSAT, the ARRL, the CGC Communicator, CQ Magazine, the FCC, the Ohio Penn DX Bulletin, Radio Netherlands, Rain, the RSGB and Australia's Q-News, that's all from the Amateur Radio Newsline(tm). Our e-mail address
is newsline@arnewsline.org. More information is available at Amateur Radio Newsline's(tm) only official website located at www.arnewsline.org. You can also write to us or support us at
Amateur Radio Newsline(tm), P.O. Box 660937, Arcadia, California 91066.

A reminder that Amateur Radio Newsline scripts are now available weekly on a self maintained list at Yahoogroups. To have a free text edition of this newscast delivered each week by e-mail go to www.yahoogroups.com, follow the

directions and sign up for the ARNewsline list.

RAIN PROMO - NOAA WEATHER MONTH

I’m Blair Alper, KA9SEQ. Whether you are a member of your local EMA, ARES, RACES, SKYWARN -- or simply weather afficianado, you no doubt have at least one weather radio handy.

RAIN kicks off its month long series of programs anout NOAA Weather Radio Services this week. Take your web browsert over to http://www.rainreport.com. You will need either a RealAudio or Windows Media player. Otherwise, pick up your telephone and call 847-827-7246.

1407. Re: Elevated Feed Vertical Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-11-02 17:45:39 UTC
From: richardharrison@webtv.net
Message-ID: <18634-3BE2DBC3-224@storefull-111.iap.bryant.webtv.net>
Source record: 155312

Roy, W7EL wrote:
"It`s a common misconception that folding an element reduces ground loss, and one that is often used to help sell antennas."

Radiation resistance is the purpose of antenna design.

Length is most important in radiation resistance but wire size and environment play important roles.

Antenna resistance is the sum of the antenna`s radiation and loss resistances. For most antennas, loss resistance in conductors is so small that it is unimportant. Resistance may be enervating for grounded antennas.

Terman says the efficiency of the antenna as a radiator is the ratio of the radiation resistance to the sum of the radiation resistance and the loss resistance (page 893, 1955 Terman). This is the old potentiometer or voltage divider formula. It appllies because the same current flows in both resistances so that the powers are proportional to the voltage drops across each resistance.

Terman says that at broadcast and higher frequencies, where 1/4-wave antennas are practical, efficiencies of 75% to 95% or more are typical.

Broadcast stations typically use 120 radials, one every 3 degrees around each tower, extending 1/4-wavelength from the tower base. For strength and protection, these typically are No. 8 AWG buried a foot or so below the surface. Radials are bare for maximum conductivity, and usually last forever, like copper plumbing.

The loss resistance of the typical AM broadcast station`s ground system is one ohm (see B. Whitfield Griffith Jr,. "Radio-Electronic Transmission Fundamentals", page 352).

Connection of radials to the earth is often mostly capacitive since the earth is often a poor conductor. Insulated wires on the surface would suffice if they didn`t get in the way.

From the Terman formula you can see that antenna efficiency is 100% if the loss resistance is zero. If the loss resistance is one ohm, the higher the radiation resistance, the higher the efficiency.

Ground resistance isn`t altered by the configuration of an antenna placed over it. The percentage of power lost in an antenna system does depend on how much of the resistance a radio "sees" is the radiation resistance and how much is the ground loss.

Best regards, Richard Harrison, KB5WZI

Unfortunately,NONE of our squirrels ever seem to get vaporized or even a tingle for that matter.

Considering we did not get one single tomato off our plants this year because of the darn squirrels, ya think we could have the electric company use those short insulators here too?

I know about 50 of them I'd like to see vaporized!

>Thanks and 73's,
>Harry

But why you want it at ground potential also has something to do with this! If you are simply putting an RFC down there to drain off precipitation static or *** maybe *** corona static from the play you sometimes get up there at the tip, that's one thing!

But if you are planning on trying that to use for lightning mitigation efforts, that's another! If that is the case, then the conductor size needed is going to make that one of the finest examples of largess ever seen in an RF choke!

You can, likely, use a pretty stout RFC that does a good enough job to accomplish the drain business. But on beyond that you'd sure seem to be better served by using a Polyphaser or other arcc gap lightning arrestor device down there across that choke, assuming that you can accomodate both the design factors needed for the working RF voltage and the available arrestor breakdown voltage at the same time.

In any event, however you feed it, you ought to contemplate putting some kind of a tank circuit out there to take care of sinking the big boy to ground! Those devices amd that neat arc gap out there on insulated tower base fed broadcast arrays ain't there because management wanted to maximize the cost of the project!

When I was a very young lad as a novice about 50 years ago I took great fun in hooking a VR150 between my vertical feed line and ground and watching it during thunderstorm passages! My Dad came in an saw me there one evening in the dark room and looked at it. He warn't no EE, but he suggested in the interest of the safety of our humble home, I might study up a bit about Ben Franklin and get keyed in on a few things. So it started by journey to learn about Dr. Zeus!

My parents' transformer just had one of those installed. They had
several outages this summer, each followed by bits of roasted
squirrel hitting the ground. IIRC they have a neighbor or three on
the same transformer... The "fix" has been working great since
about the end of august.

I bought this for a crank up tower but it will not fit! This is the biggest
of the amateur rotators. You can see the specs at:
http://www.prosistel.net/home-e/default_net.html
Look at the menu on the left and click on PST-71

This is new, never used, with the model B control box, all hardware,
and manual.

I paid $1500 for it and will ship it CONUS for $1200 total.

73,
Chuck...K1KW

Ha ha ha ha!
I know what you mean. Every year I try to outsmart the local
smarty pants squirrels that get to my bird feeder. I have one that
closes up when a sqirrel gets on it but they found a way around that.
I watched as they climbed my clothes line pole and then jump through
the air and BANG the top of the feeder on the way by. That would shake
a bunch of bird feed to the ground and they would repeat this and eat like
gluttens all day. I put 2 metal plates on top of the clothed line pole and
hooked them up to 110 AC. HA HA HA! It didn't hurt the squirrels but once
they had tasted AC, they stopped going up the pole!
Ha! Take that mister smarty pants squirrel!

Mike,
Yes my only intent with the coil was to drain off static charges. I have already been thinking of forming
a gap next to the mast tied to some ground stakes for some sort of lightning protection. I am also putting
a connector in the feedline outside the house so I can disconnect the feedline and gound it.

Thanks,
Harry

Yes, and the larger the inductance, the larger the impediment to lightning, and the less that is shunted to ground through the choke.

10 x the feed impedance at your lowest operating frequency should not severly impact your operations. 1 mhy is 6280 ohms at 1 MHz. You could wind such a coil with 4-inches of coil length using No. 20 AWG closewound on a 4-inch dia. form (by my ARRL Lightning Coil Calculator).

Working many years in broadcast stations, I never saw arc-gaps across tower base insulators fire. The Faraday shields, on the other hand, in the dog houses, always were pock marked from lightning much as the moon is pitted.

Tower lighting chokes not only kept r-f out of the a-c supply, they kept any serious lightning out of the a-c supply too.

Faraday shields not only kept harmonics off the antennas, they kept lightning from any serious access to transmission lines and transmitters. We never had any lightning damage from thousands of direct hits.

Best regards, Richard Harrison, KB5WZI

Hi There,

If the GP3 is the one that covers 10/15/20 then that's the one I've got. In my opinion it works well on 10 and 20 (Normally two S points at least better than my wire doublet at the same height) but is not very effective at all on 15m, I've had trouble getting a good match on 15. Spoke to another station a couple of weeks back who had the same problem with 15m. Other than that not a bad antenna, it will also tune to 12m, just make sure that you've got space to run the three wire radials out (1/4 wavelength for each band).

Same thing as installing a 50-ohm pad between a generator and a load. If the coax has a characteristic impedance of 50 ohms and exhibits 3 dB of loss, it makes a very nice 3-dB pad.

There's an outfit (yankee something) that makes an anti-squirrel feeder.
The trick is that the part that you have to sit on (or grip) to get at the
food is motorized, and after a certain weight, it begins to spin. After
that, it's up to the squirrel what radial vector he'd like to take.
Less hazardous, and probably more fun to watch than the 110 route.

Can someone tell me if there is a way to make a beam and a dipole, two separate antennas, that can be fed with 100 ohm coax.
Basically I want to make an antenna setup with one dipole and one beam each off one common main feedline.
I want the power to come along one feedline, be split into two feedlines, hence the 100 ohm coax and then feed two separate antennas, each fed from one of the 100 ohm coax lines.
Are there driven elements that have feed points of 100 ohms??
Larrry ve3fxq

1426. Re: Elevated Feed Vertical Antenna

Source record: 155332

I disagree that radiation resistance is the purpose of antenna design. The purpose is to radiate and receive RF. You can get a wide range of radiation resistance values with any antenna without changing its ability to radiate and receive RF.

I feel that the quoted posting implies that folding an antenna will change the radiation resistance without changing the loss resistance, thereby increasing the efficiency. Let's work through an example with numbers.

I'll begin with a base fed unfolded monopole antenna having zero ground loss, so we can see what happens to the ground current without knowing how the ground loss is transformed. I'll use exactly 36 ohms as base radiation resistance for simplicity, will assume that the antenna's resonant, and will ignore conductor losses (which in most cases will be much less than the ground system resistance, and insignificant). We'll apply 144 watts to make numbers come out even.

The feedpoint resistance is 36 ohms, so the current at the base is sqrt(P/R) = sqrt(144/36) = 2.0 amps RMS. To base feed the antenna, we connect one conductor of the feedline to the base of the antenna and the other to the ground system. So the current flowing into the ground system is also 2.0 amps RMS. All the applied 144 watts is radiated.

Now let's fold the monopole. The feedpoint impedance increases by a factor of 4, to 144 ohms. Consequently, the current at the feedpoint is now sqrt(144/144) = 1.0 amp RMS. This makes sense -- 1.0 amp flows in each of the two conductors, and the two currents are in phase, so we now have half the current as before flowing in twice the number of conductors as before, resulting in the same field strength and pattern. But what's the ground current? Well, there's 1.0 amp from the feedline connection as before. But now there's also 1.0 amp from the second antenna conductor, where it's connected to ground. These two currents are in phase, so a total of 2.0 amps is entering the ground system.

The same amount of current is flowing in the ground system as for the unfolded monopole. If the ground system had resistance, wouldn't you expect the loss, I^2*R, to be the same for both?

So let's give the ground system some resistance, say 5 ohms, and change the power to 164 watts for convenience.

Starting with an unfolded monopole, the total feedpoint resistance is 36 + 5 = 41 ohms. The current at the feedpoint = sqrt(P/R) = sqrt(164/41) = 2.0 amps RMS. The current flowing into the ground system is also 2.0 amps RMS. The power radiated = (2.0)^2 * 36 = 144 watts, and the power

dissipated in the ground system = (2.0)^2 * 5 = 20 watts. The sum of these two is 164 watts, which is the total power applied. The efficiency is 144/164 = 87.8%. You can use the common formula for efficiency = Rr/(Rr + Rl) to get the same result: efficiency = 36/(36 + 5) = 87.8%. But -- here's the important part -- the DEFINITION of efficiency isn't the formula. The definition of efficiency is the fraction of the applied power which is radiated. We applied 164 watts, and 144 were radiated. That's what counts.

Now let's fold the antenna. The radiation resistance, as measured at the feedpoint, is 4 * 36 = 144 ohms. But what's the total feedpoint resistance? 144 + 5 ohms? Or 144 + 4 * 5 = 164 ohms? Suppose the radiation resistance was transformed but the loss resistance wasn't, resulting in a feedpoint resistance of 144 + 5 = 149 ohms. The feedpoint current (for 164 watts applied) would be sqrt(164/149) = 1.049 amps. The radiated power would therefore be (1.049)^2 * 144 = 158.5 watts. The ground current = 2 * 1.049 = 2.098 amps. This flows through the same 5 ohms of ground resistance as before, producing a loss of (2.098)^2 * 5 = 22.0 watts. There's a problem here, though. We're applying 164 watts. 158.5 are radiated and 22.0 are dissipated in the ground. That's 180.5 watts. Oops. Sorry, folks, that can happen in marketing departments, but not in engineering.

The fact is that both the radiation and loss resistances are transformed by a factor of four at the feedpoint. The folded monopole feedpoint resistance is 164, not 149 ohms. The feedpoint current is 1.0 amp, resulting in a radiated power of 144 watts. The total ground current is 2.0 amps, flowing through 5 ohms of loss resistance, resulting in a loss of 20 watts. The sum of these two is -- whew -- 164 watts, the applied power. The efficiency -- the fraction of the applied power that's radiated -- is exactly the same as for the unfolded monopole.

Looking at the feedpoint and its 164 ohms of resistance, 144 of these are radiation resistance. The remaining 20 are the loss resistance. Again, you can use the formula for efficiency if you wish -- using 144 for Rr and 20 for Rl -- and you'll get the right result. The common trap is to use 144 ohms, the radiation resistance at the feedpoint, for Rr, and 5, the ground system resistance not at the feedpoint but at the ground system connection, for Rl. The result you get from this calculation isn't the efficiency. The efficiency is the fraction of the applied power which is radiated, which we've found to be 144/164 = 87.8%. Whatever formula you use, and whatever values you plug into it, it had better give the same results as an analysis based on the actual powers being radiated and lost. Or it's wrong.

My challenge is this: If anyone thinks that folding an antenna will improve the efficiency (neglecting conductor loss), do an analysis like I've done here. Show the currents at each point and calculate the powers radiated and dissipated. Show that the efficiency is better when the antenna is folded. But remember, the radiated and dissipated powers had better add up to the applied power. Good luck!

I take it the beam and the dipole are for the same frequency?

Bondo works well.

I use a 7" long, ultra thin Comet antenna, I don't remember the letter it begins with, but it's number is 3. (HT is not available at moment to check. I think Pryme has a similar model. It is for 2M and 440 and works notably better than the original antenna on those two bands. It also performs about the same on my new Kenwood TH-F6.

I agree, a full length ball mount whip is the best but if you want a
mag-mount, you might want to try a Wilson 5000 CB Antenna with the
whip adjusted for 10 meters. They aren't cheap, about $75. My CB
friends swear by them.

Correction to my earlier reply: I use a Comet SMA-503, an excellent
antenna. The Premier RD-9SMA is a good substitute.

death to all vermits!

Never seen a toasted varmit, but sounds like a good idea.
They've won the bird-feeder battle in our neighborhood.
My biggest problem was a nasty Possum that'd come
around when I was working "portable" from my carport;
That bastard would come around while I was enjoying nice
summer late nite weather on the carport (instead of cooped
up in the basement) and hiss at me as he went past. Many's
the time I was tempted to heave my MFJ tuner at him. Trying
